

Lecture 11

Shortest Paths

Department of Computer Science
Hofstra University

Lecture Goals

- In this lecture we study **shortest-paths** problems. We begin by analyzing some basic properties of shortest paths and a generic algorithm for the problem.
- We introduce and analyze **Dijkstra's algorithm** for shortest-paths problems with nonnegative weights.
- Next, we consider **Topological Sort** for Edge-weighted DAG, which works even if the weights are negative.
- We conclude with the **Bellman–Ford** algorithm for edge-weighted digraphs with no negative cycles.
- We conclude with the Floyd Warshall Algorithm for all-pairs shortest path

Shortest Paths in an Edge-weighted Digraph

Given an edge-weighted digraph, find the shortest path from s to t .

edge-weighted digraph

4→5	0.35
5→4	0.35
4→7	0.37
5→7	0.28
7→5	0.28
5→1	0.32
0→4	0.38
0→2	0.26
7→3	0.39
1→3	0.29
2→7	0.34
6→2	0.40
3→6	0.52
6→0	0.58
6→4	0.93

shortest path from 0 to 6

0→2	0.26
2→7	0.34
7→3	0.39
3→6	0.52

Variants

❖ Which vertices?

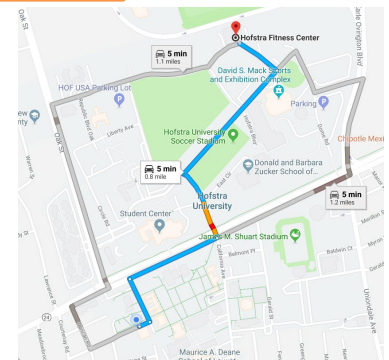

- Single source: from one vertex s to every other vertex.
- Source-sink: from one vertex s to another t .
- All pairs: between all pairs of vertices.

❖ Nonnegative weights?

❖ Cycles?

- Negative cycles.

Can we use BFS?

Simplifying assumption: Each vertex is reachable from s .

Weighted Directed Edge API

```
public class DirectedEdge
```

```
    DirectedEdge(int v, int w, double weight) //weighted edge v->w
```

```
    int from() // vertex v
```

```
    int to() // vertex w
```

```
    double weight() // the weight
```

```
    String toString() // string representation
```

Idiom for processing an edge *e*: `int v = e.from(), w = e.to();`

Weighted Edge: Java Implementation

```
public class DirectedEdge
{
    private final int v, w;
    private final double weight;

    public DirectedEdge(int v, int w, double weight)
    {
        this.v = v;
        this.w = w;
        this.weight = weight;
    }

    public int from()
    { return v; }

    public int to()
    { return w; }

    public int weight()
    { return weight; }
}
```

Edge-Weighted Graph API

```
public class EdgeWeightedDigraph
```

```
    EdgeWeightedDigraph(int V) // edge-weighted digraph with V vertices
```

```
    void addEdge(DirectedEdge e) // add weighted directed edge e
```

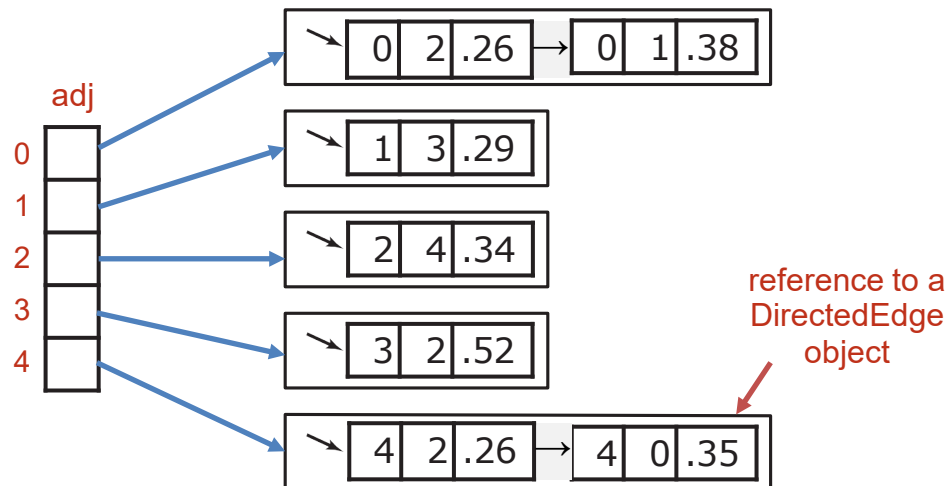

```
    Iterable<DirectedEdge> adj(int v) // edges pointing from v
```

```
    Iterable<DirectedEdge> edges() // all edges in this graph
```

```
    int V() // number of vertices
```

```
    int E() // number of edges
```

```
    String toString() // string representation
```

Edge-Weighted Digraph: Adjacency-Lists Implementation

```
public class EdgeWeightedDigraph
{
    private final int V;
    private final List<DirectedEdge>[] adj;

    public EdgeWeightedDigraph (int V)
    {
        this.V = V;
        adj = (List<DirectedEdge>[]) new ArrayList[V];
        for (int v = 0; v < V; v++)
            adj[v] = new ArrayList<DirectedEdge>();
    }

    public void addEdge(DirectedEdge e)
    {
        int v = e.from();
        adj[v].add(e);
    }

    public Iterable<DirectedEdge> adj(int v)
    {
        return adj[v];
    }
}
```

← add edge $e = v \rightarrow w$ to
only v 's adjacency lists

Single-source Shortest Paths API

Goal. Find the shortest path from s to every other vertex.

```
public class SP
```

```
    SP(EdgeWeightedGraph G, int s) // shortest paths from s in graph G
```

```
    double distTo(int v) // length of shortest path from s to v
```

```
    Iterable<DirectedEdge> pathTo(int v) // shortest path from s to v
```

```
SP sp = new SP(G, s);
for (int v = 0; v < G.V(); v++)
{
    StdOut.printf("%d to %d (0.2f): ", s, v, sp.distTo(v));
    for (DirectedEdge e : sp.pathTo(v)) {
        StdOut.print(e + " ");
        StdOut.println();
    }
}
```

```
0 to 0 (0.00):
0 to 1 (1.05): 0->4 0.38 4->5 0.35 5->1 0.32
0 to 2 (0.26): 0->2 0.26
0 to 3 (0.99): 0->2 0.26 2->7 0.34 7->3 0.39
0 to 4 (0.38): 0->4 0.38
0 to 5 (0.73): 0->4 0.38 4->5 0.35
0 to 6 (1.51): 0->2 0.26 2->7 0.34 7->3 0.39 3->6 0.52
0 to 7 (0.60): 0->2 0.26 2->7 0.34
```

Data Structures for Single-source Shortest Paths

Goal. Find the shortest path from s to every other vertex.

Observation. A shortest-paths tree (SPT) solution exists.

Consequence. Can represent the SPT with two vertex-indexed arrays:

- $\text{distTo}[v]$ is length of shortest path from s to v .
- $\text{edgeTo}[v]$ is last edge on shortest path from s to v .

shortest-paths tree from 0

	edgeTo[]	distTo[]
0	null	0
1	5->1 0.32	1.05
2	0->2 0.26	0.26
3	7->3 0.37	0.97
4	0->4 0.38	0.38
5	4->5 0.35	0.73
6	3->6 0.52	1.49
7	2->7 0.34	0.60

parent-link representation

```
public double distTo(int v)
{ return distTo[v]; }

public Iterable<DirectedEdge> pathTo(int v)
{
    Stack<DirectedEdge> path = new Stack<DirectedEdge>();
    for (DirectedEdge e = edgeTo[v]; e != null; e = edgeTo[e.from()])
        path.push(e);
    return path;
}
```

Edge Relaxation

Relax edge $e = v \rightarrow w$. (basic of building SPT)

- $\text{distTo}[v]$ is length of shortest **known** path from s to v .
- $\text{distTo}[w]$ is length of shortest **known** path from s to w .
- $\text{edgeTo}[w]$ is last edge on shortest **known** path from s to w .
- If $e = v \rightarrow w$ gives shorter path to w through v , update $\text{distTo}[w]$ and $\text{edgeTo}[w]$.
 - $\text{distTo}[w] = \min(\text{distTo}[w], \text{distTo}[v] + e.\text{weight}());$

```
private void relax(DirectedEdge e)
{
    int v = e.from(), w = e.to();
    if (distTo[w] > distTo[v] + e.weight())
    {
        distTo[w] = distTo[v] + e.weight();
        edgeTo[w] = e;
    }
}
```

OLD $\text{distTo}[w] = 7.2 > \text{distTo}[v] + e.\text{weight}() = 3.1 + 1.3 = 4.4$

NEW $\text{distTo}[w] \leftarrow \text{distTo}[v] + e.\text{weight}() = 4.4$

Generic Shortest-paths Algorithm

Generic algorithm (to compute SPT from s)

For each vertex v : $\text{distTo}[v] = \infty$.

For each vertex v : $\text{edgeTo}[v] = \text{null}$.

$\text{distTo}[s] = 0$.

Repeat until done:

- Relax any edge.

Proposition. Generic algorithm computes SPT (if it exists) from s .

Pf.

- Throughout algorithm, $\text{distTo}[v]$ is the length of a simple path from s to v (and $\text{edgeTo}[v]$ is last edge on path).
- Each successful relaxation decreases $\text{distTo}[v]$ for some v .
- The entry $\text{distTo}[v]$ can decrease at most a finite number of times.

Efficient implementations. How to choose which edge to relax?

- Ex 1. Dijkstra's algorithm. (**nonnegative weights, directed cycles**).
- Ex 2. Bellman–Ford algorithm. (**no negative cycles**).

Dijkstra's Algorithm

- Initialization:
 - Set the distance to the source node as 0 and to all other nodes as infinity.
 - Mark all nodes as unvisited and store them in a priority queue.
- Main Loop:
 - Extract the **unvisited node** with **the smallest known distance** from the queue.
 - For each neighboring node, calculate its tentative distance through the current node. **If this distance is smaller than the previously recorded distance, update it with relaxation.**
 - Mark the current node as visited once all its neighbors are processed.
- Termination:
 - The algorithm continues until all reachable nodes are visited, or until the shortest path to a specific destination is found.

Dijkstra's Algorithm: Correctness Proof

Proposition. Dijkstra's algorithm computes a SPT in any edge-weighted digraph with nonnegative weights.

Pf.

- Each edge $e = v \rightarrow w$ is relaxed exactly once (when v is relaxed),
 - leaving $\text{distTo}[w] \leq \text{distTo}[v] + e.\text{weight}()$.
- Inequality holds until algorithm terminates because:
 - $\text{distTo}[w]$ cannot increase  $\text{distTo}[]$ values are monotone decreasing
 - $\text{distTo}[v]$ will not change  we choose lowest $\text{distTo}[]$ value at each step (and edge weights are nonnegative)
- Thus, upon termination, shortest-paths optimality conditions hold.

Example Graph

Initialize

2. Assign to all nodes a tentative distance value

Visited Nodes: []

Unvisited Nodes: [A, B, C, D, E, F]

Node	Shortest Distance	Previous Node
A	0	
B	∞	
C	∞	
D	∞	
E	∞	
F	∞	

Visit Node A

3. For the current node calculate the distance to all unvisited neighbours

3.1. Update shortest distance, if new distance is shorter than old distance

Visited Nodes: []

Unvisited Nodes: [A, B, C, D, E, F]

Node	Shortest Distance	Previous Node
A	0	
B	2	A
C	∞	
D	8	A
E	∞	
F	∞	

OLD $\text{distTo}[B] = \infty > \text{distTo}[A] + e[A][B].\text{weight}() = 0 + 2 = 2$

NEW $\text{distTo}[B] \leftarrow \text{distTo}[A] + e[A][B].\text{weight}() = 2$

OLD $\text{distTo}[D] = \infty > \text{distTo}[A] + e[A][D].\text{weight}() = 0 + 8 = 8$

NEW $\text{distTo}[D] \leftarrow \text{distTo}[A] + e[A][D].\text{weight}() = 8$

Visit Node B

3. For the current node calculate the distance to all unvisited neighbours
3.1. Update shortest distance, if new distance is shorter than old distance

Visited Nodes: [A]

Unvisited Nodes: [B, C, D, E, F]

Node	Shortest Distance	Previous Node
A	0	
B	2	A
C	∞	
D	7	B
E	8	B
F	∞	

OLD $\text{distTo}[D] = 8 > \text{distTo}[B] + e[B][D].\text{weight}() = 2+5 = 7$
NEW $\text{distTo}[D] \leftarrow \text{distTo}[B] + e[B][D].\text{weight}() = 7$
OLD $\text{distTo}[E] = \infty > \text{distTo}[B] + e[B][E].\text{weight}() = 2+6 = 8$
NEW $\text{distTo}[E] \leftarrow \text{distTo}[B] + e[B][E].\text{weight}() = 8$

Visit Node D

3. For the current node calculate the distance to all unvisited neighbours
3.1. Update shortest distance, if new distance is shorter than old distance

Node	Shortest Distance	Previous Node
A	0	
B	2	A
C	∞	
D	7	B
E	8	B
F	9	D

OLD $\text{distTo}[E] = 8 < \text{distTo}[D] + e[D][E].\text{weight}() = 7+3 = 10$
No update, $\text{distTo}[E]$ stays 8
OLD $\text{distTo}[F] = \infty > \text{distTo}[D] + e[D][F].\text{weight}() = 7+2 = 9$
NEW $\text{distTo}[F] \leftarrow \text{distTo}[D] + e[D][F].\text{weight}() = 9$

Visit Node E

3. For the current node calculate the distance to all unvisited neighbours

3.1. Update shortest distance, if new distance is shorter than old distance

Visited Nodes: [A, B, D] Unvisited Nodes: [C, E, F]

Node	Shortest Distance	Previous Node
A	0	
B	2	A
C	17	E
D	7	B
E	8	B
F	9	D

OLD $\text{distTo}[C] = \infty > \text{distTo}[E] + e[E][C].\text{weight}() = 8 + 9 = 17$

NEW $\text{distTo}[C] \leftarrow \text{distTo}[E] + e[E][C].\text{weight}() = 17$

OLD $\text{distTo}[F] = 9 = \text{distTo}[E] + e[E][F].\text{weight}() = 8 + 1 = 9$

No update, $\text{distTo}[F]$ stays 9

Visit Node F

3. For the current node calculate the distance to all unvisited neighbours

3.1. Update shortest distance, if new distance is shorter than old distance

Visited Nodes: [A, B, D, E] Unvisited Nodes: [C, F]

Node	Shortest Distance	Previous Node
A	0	
B	2	A
C	12	F
D	7	B
E	8	B
F	9	D

OLD $\text{distTo}[C] = 17 > \text{distTo}[F] + e[F][C].\text{weight}() = 9 + 3 = 12$

NEW $\text{distTo}[C] \leftarrow \text{distTo}[F] + e[F][C].\text{weight}() = 12$

Visit Node C

Nothing changes, since C has no unvisited neighbor nodes

End of Algorithm

- Table contains the shortest distance to each node N from the source node A, and its previous node in the shortest path

4. Mark current node as visited

Visited Nodes: [A, B, D, E, F, C] Unvisited Nodes: []

Node	Shortest Distance	Previous Node
A	0	
B	2	A
C	12	F
D	7	B
E	8	B
F	9	D

Getting the Shortest Path from A to C

- C's previous node is F; F's previous node is D; D's previous node is B; B's previous node is A
- Shortest Path from A to C is ABDFC

Get shortest path from A to C

Node	Shortest Distance	Previous Node
A	0	
B	2	A
C	12	F
D	7	B
E	8	B
F	9	D

Dijkstra's Algorithm Example 2

- Consider vertices in increasing order of distance from s
 - (non-tree vertex with the lowest distTo[] value).
- Add vertex to tree and relax all edges pointing from that vertex.

choose source vertex 0
relax all edges adjacent from 0
choose vertex 1
relax all edges adjacent from 1

choose vertex 7
relax all edges adjacent from 7
choose vertex 4
relax all edges adjacent from 4

choose vertex 5
relax all edges adjacent from 5
choose vertex 2
relax all edges adjacent from 2
choose vertex 3
relax all edges adjacent from 3
choose vertex 6
relax all edges adjacent from 6

Bellman-Ford Algorithm

- Initialize distance array `distTo[]` for each vertex `v` as **`distTo[v] = ∞`**, and **`distTo[s] = 0`** to source vertex `s`.
- Relax all **edges** $|V|-1$ times.

```
private void relax(DirectedEdge e)
{
    int v = e.from(), w = e.to();
    if (distTo[w] > distTo[v] + e.weight())
    {
        distTo[w] = distTo[v] +
            e.weight();
        edgeTo[w] = e;
    }
}
```

Recall:

Generic algorithm (to compute SPT from `s`)

For each vertex `v`: `distTo[v] = ∞`.

For each vertex `v`: `edgeTo[v] = null`.

`distTo[s] = 0`.

Repeat until done:

- Relax any edge.

Bellman-Ford algorithm

For each vertex `v`: `distTo[v] = ∞`.

For each vertex `v`: `edgeTo[v] = null`.

`distTo[s] = 0`.

Repeat $|V| - 1$ times:

- Relax each edge.

Bellman-Ford Algorithm Proof of Correctness

- Relaxing edges $|V|-1$ times in the Bellman-Ford Algorithm guarantees that the algorithm has explored all possible paths of length up to $|V|-1$, which is the maximum possible length of a shortest path in a graph with $|V|$ vertices. This allows the algorithm to correctly calculate the shortest paths from the source vertex to all other vertices, **given that there are no negative-weight cycles**.

Bellman-Ford Algorithm with Negative Cycle Detection

- Initialize distance array `distTo[]` for each vertex `v` as **`distTo[v] = ∞`**, and **`distTo[s] = 0`** to source vertex `s`.
- Relax all **edges** $|V|-1$ times.
- Relax all the edges one more time i.e. the **N-th** time:
 - Case 1 (Negative cycle exists): if any edge can be further relaxed, i.e., for any **edge e**, if **`distTo[w] > distTo[v] + e.weight()`**
 - Case 2 (No Negative cycle) : case 1 fails for all the edges.

Time Complexity of Bellman-Ford Algorithm

- Time complexity for connected graph:
- Best Case: $O(|E|)$, when distance array after 1st and 2nd relaxation are same, we can simply stop further processing after one iteration
- Average Case: $O(|V|*|E|)$
- Worst Case: $O(|V|*|E|)$
 - If the graph is complete, the value of E becomes $O(|V|^2)$. So overall time complexity becomes $O(|V|^3)$

SPT

Bellman-Ford Algorithm Example 3 w. Negative Cycle

- Step 1: Initialize a distance array $\text{Dist}[]$ to store the shortest distance for each vertex from the source vertex. Initially distance of source will be 0 and Distance of other vertices will be INFINITY. $\text{distTo}[N] = \infty$

Initialize The Distance Array

Distance Array
 $\text{Dist}[]$

A	B	C	D	E	F
0	∞	∞	∞	∞	∞

- Step 2: Start relaxing the edges, during 1st relaxation:
- OLD $\text{distTo}[B] = \infty > \text{distTo}[A] + e[A][B].\text{weight}() = 0 + 5 = 5$
- NEW $\text{distTo}[B] = \text{distTo}[A] + e[A][B].\text{weight}() = 5$

1st Relaxation Of Edges

- Step 3: During 2nd relaxation:
- OLD $\text{distTo}[D] = \infty > \text{distTo}[B] + e[B][D].\text{weight}() = 5+2 = 7$
- NEW $\text{distTo}[D] \leftarrow \text{distTo}[B] + e[B][D].\text{weight}() = 7$
- OLD $\text{distTo}[C] = \infty > \text{distTo}[B] + e[B][C].\text{weight}() = 5+1 = 6$
- NEW $\text{distTo}[C] \leftarrow \text{distTo}[B] + e[B][C].\text{weight}() = 6$

2nd Relaxation Of Edges

- Step 4: During 3rd relaxation:
- OLD $\text{distTo}[F] = \infty > \text{distTo}[D] + e[D][F].\text{weight}() = 7+2 = 9$
- NEW $\text{distTo}[F] \leftarrow \text{distTo}[D] + e[D][F].\text{weight}() = 9$
- OLD $\text{distTo}[E] = \infty > \text{distTo}[C] + e[C][E].\text{weight}() = 6+1 = 7$
- NEW $\text{distTo}[E] \leftarrow \text{distTo}[C] + e[C][E].\text{weight}() = 7$

3rd Relaxation Of Edges

- Step 5: During 4th relaxation:
- OLD $\text{distTo}[D] = 7 > \text{distTo}[E] + e[E][D].\text{weight}() = 7 - 1 = 6$
- NEW $\text{distTo}[D] \leftarrow \text{distTo}[E] + e[E][D].\text{weight}() = 6$
- OLD $\text{distTo}[E] = 7 > \text{distTo}[F] + e[F][E].\text{weight}() = 9 - 3 = 6$
- NEW $\text{distTo}[E] \leftarrow \text{distTo}[F] + e[F][E].\text{weight}() = 6$

4th Relaxation Of Edges

- Step 6: During 5th relaxation:
- OLD $\text{distTo}[F] = 9 > \text{distTo}[D] + e[D][F].\text{weight}() = 6+2 = 8$
- NEW $\text{distTo}[D] \leftarrow \text{distTo}[D] + e[D][F].\text{weight}() = 8$
- OLD $\text{distTo}[D] = 6 > \text{distTo}[E] + e[E][D].\text{weight}() = 6-1 = 5$
- NEW $\text{distTo}[E] \leftarrow \text{distTo}[E] + e[E][D].\text{weight}() = 5$
- Since the graph has 6 vertices, So during the 5th relaxation the shortest distance for all the vertices should have been calculated.

5th Relaxation Of Edges

- Step 7: Now the final relaxation i.e. the 6th relaxation should indicate the presence of negative cycle if there is any changes in the distance array of 5th relaxation.
- During the 6th relaxation, following changes can be seen:
- OLD $\text{distTo}[E] = 6 > \text{distTo}[F] + e[F][E].\text{weight}() = 8 - 3 = 5$
- NEW $\text{distTo}[D] \leftarrow \text{distTo}[F] + e[F][E].\text{weight}() = 5$
- OLD $\text{distTo}[F] = 8 > \text{distTo}[D] + e[D][F].\text{weight}() = 5 + 2 = 7$
- NEW $\text{distTo}[E] \leftarrow \text{distTo}[D] + e[D][F].\text{weight}() = 7$
- Since, we observe changes in the Distance array. Hence, we can conclude the presence of a negative cycle in the graph (D \rightarrow F \rightarrow E).

Detecting The Negative Edge By 6Th Relaxation Of Edges

Dijkstra's Algorithm vs. Bellman-Ford Algorithm

- Dijkstra's Algorithm:
 - Uses a priority queue to select the next vertex to process.
 - Greedily selects the vertex with the smallest tentative distance to source node.
 - Works only on graphs with non-negative edge weights.
 - Time complexity of $O(V^2)$ for a dense graph and $O(E \log V)$ for a sparse graph.
- Bellman-Ford Algorithm:
 - Iteratively relaxes all edges $V-1$ times, where V is the number of vertices.
 - Does not use a priority queue.
 - Can handle graphs with negative edge weights, and can detect negative cycles.
 - Time complexity of $O(VE)$, where V is the number of vertices and E is the number of edges in the graph.
- Dijkstra's algorithm is faster and more efficient for graphs with non-negative weights, the Bellman-Ford Algorithm Example 1 is more versatile as it can handle negative weights and detect negative cycles, albeit at the cost of lower efficiency.

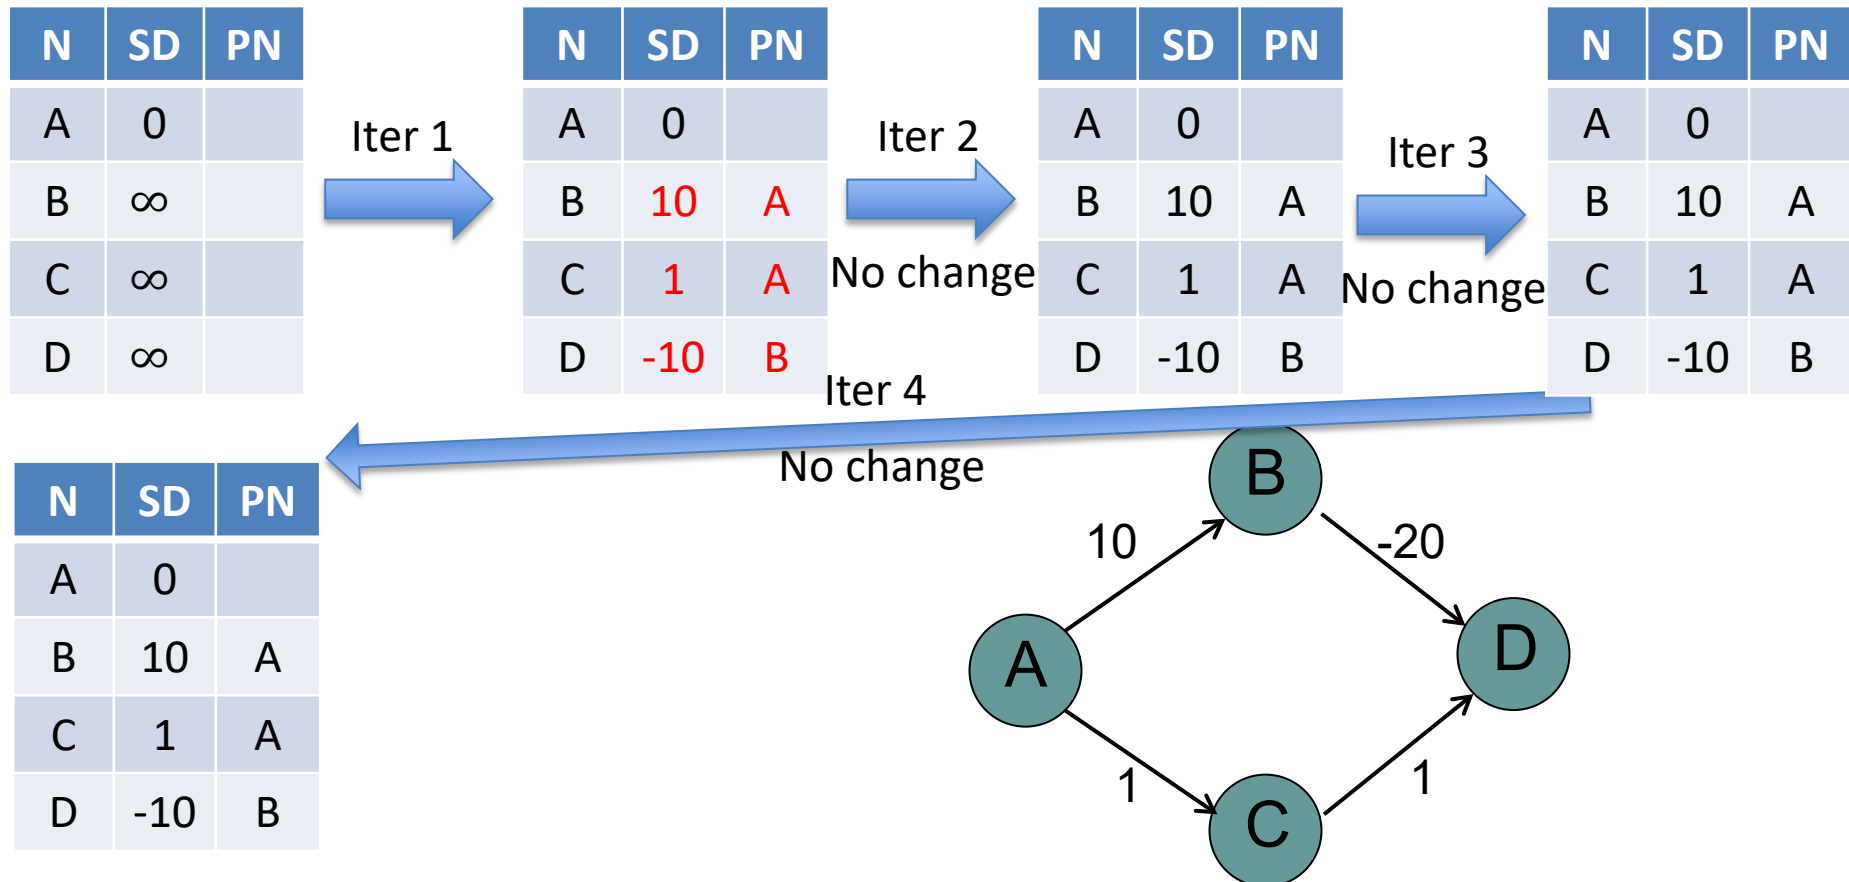

Dijkstra's Algorithm does not work for Negative Edge Weights

- Dijkstra's Algorithm is greedy and optimal: any node that has been visited should have its shortest distance to the source. After visiting A, C, D, we have got D's shortest distance to A is 2, but after visiting D, D's distance to A is updated to -10, which violates the greedy optimal assumption of Dijkstra's Algorithm.

Bellman Ford Algorithm works for Negative Edge Weights

- We run for $V-1=3$ iterations, then run one more iteration with no change. Hence we conclude that The Bellman-Ford algorithm successfully calculated the shortest paths from node A to all other nodes. The shortest path from node A to node D goes through node B with a total cost of -10. There are no negative weight cycles.

Quiz

- Which of the following algorithm can be used to efficiently calculate single source shortest paths in a Directed Acyclic Graph?
 - Dijkstra
 - Bellman-Ford
 - Topological Sort
 - Strongly Connected Component
- ANS: Topological Sort
- Using Topological Sort, we can find single source shortest paths in $O(V+E)$ time which is the most efficient algorithm

Quiz

- Given a graph where all edges have positive weights, the shortest paths produced by Dijkstra and Bellman Ford algorithm may be different but path weight would always be same.
- ANS: True
- Dijkstra and Bellman-Ford both work fine for a graph with all positive weights, but they are different algorithms and may pick different edges for shortest paths.

Quiz

- Match the following
 - Group A
 - a) Dijkstra's single shortest path algo
 - b) Bellman Ford's single shortest path algo
 - c) Floyd Warshall's all pair shortest path algo
 - Group B
 - p) Dynamic Programming
 - q) Backtracking
 - r) Greedy Algorithm
- Dijkstra is a greedy algorithm where we pick the minimum distant vertex from not yet finalized vertices. Bellman Ford and Floyd Warshall both are Dynamic Programming algorithms where we build the shortest paths in bottom up manner.

Quiz

- Let G be a directed graph whose vertex set is the set of numbers from 1 to 100. There is an edge from a vertex i to a vertex j if either $j = i + 1$ or $j = 3i$. The minimum number of edges in a path in G from vertex 1 to vertex 100 is
- A. 4 B. 7 C. 23 D. 99
- ANS: 7
- The task is to find minimum number of edges in a path in G from vertex 1 to vertex 100 such that we can move to either $i+1$ or $3i$ from a vertex i .
- Since the task is to minimize number of edges, we would prefer to follow $3*i$. Let us follow multiple of 3. $1 \Rightarrow 3 \Rightarrow 9 \Rightarrow 27 \Rightarrow 81$, now we can't follow multiple of 3 anymore. So we will have to follow $i+1$. This solution gives a long path.
- What if we begin from end, and we reduce by 1 if the value is not multiple of 3, else we divide by 3. $100 \Rightarrow 99 \Rightarrow 33 \Rightarrow 11 \Rightarrow 10 \Rightarrow 9 \Rightarrow 3 \Rightarrow 1$
- So we need total 7 edges.
