

Lecture 10

Basic Graph Algorithms

Department of Computer Science
Hofstra University

Lecture Goals

- Compare the **Graph ADT** with other ADTs
- Define **basic notions** associated with graphs
- Implement graphs using an **adjacency matrix** representation and an **adjacency list** representation
- We introduce two classic algorithms for searching a graph—**depth-first search** and **breadth-first search**.
- we introduce a depth-first search based algorithm for computing the **topological sort** of an acyclic digraph.

ADT of Graph

Unstructured structures

Sets

Sequential, linear structures

Arrays, linked lists

Hierarchical structures

Trees

Useful for

- iterating over all elements,
- accessing via index

Can indicate common structure in key

- for example, the prefix in tire

Principle: Basic objects & Relationships between them

Graph is a generalization of this principle

Basic objects: vertices, nodes

Relationships between them: edges, arcs, links

Examples of Graphs

Basic objects: we

Relationships between

Basic objects: people

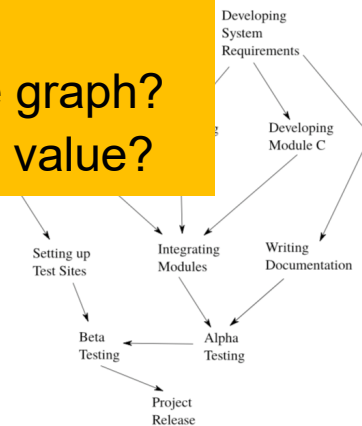

Relationships between them: friends

Relationships between them: nonstop flights

Some general questions related to graphs:

- How to create a graph?
- Are two vertices adjacent?
- Is the graph dense? sparse?
- How far are two vertices in the graph?
- How many components are there in the graph?
- Can we find a vertex with particular key value?

Basic objects: tasks

Relationships between them: dependencies

Graph Definitions

Basic objects: vertices, nodes

Relationships between them: edges, arcs, links

V

Size of graph: $|V| + |E|$

$|V|$: number of vertices

E

$|E|$: number of edges

Undirected

edges are symmetric

Directed

Weighted

cost

Neighbor: u is a neighbor of v if:
there is an edge from u to v
OR
there is an edge from v to u

What are the neighbors of the vertex 4?

- A. 3,4,5,6
- ☒ B. 3,5,6
- C. 3,6
- D. 5

Path: sequence of vertices and edges that depicts hopping along graph

For which pair of vertices is there a path in the graph starting at the first and ending at the second?

- A. vertex 1 and vertex 3
- B. vertex 4 and vertex 6
- ☒ C. vertex 6 and vertex 5

What's the maximum number of edges in a **directed** and **undirected** graph with n vertices?

$n*(n-1)$ for the **directed** graph and $n*(n-1)/2$ for the **undirected** graph (i.e. edges from a node back to itself).

- Assume there is at most one edge from a given start vertex to a given end vertex.

Implementing Graphs in Java

Basic objects: vertices, nodes ← Label by integers

Relationships between them: edges, arcs, links

```
public abstract class Graph {  
    private int numVertices;  
    private int numEdges;  
  
    public Graph() {  
        numVertices = numEdges = 0;  
    }  
  
    public int getNumVertices() {  
        return numVertices;  
    }  
  
    public int getNumEdges() {  
        return numEdges;  
    }  
  
    public void addVertex() {  
        implementAddVertex();  
        numVertices++;  
    }  
  
    public abstract void implementAddVertex();  
    public abstract List<Integer> getNeighbors(int v);  
}
```

size of a graph

data associated with any graph

methods that ought to be available with any graph.

leave implementation of key functionalities to subclasses

For example, which cities we can reach with nonstop flight?

Graph Representation: Adjacency Matrix

Column index

array entry > 1:
- multiple edges,
- or weighted edges

	0	1	2	3	4	5
0	0	1	0	0	0	0
1	0	0	0	0	0	0
2	0	0	0	1	0	0
3	0	0	0	0	0	0
4	0	0	0	1	0	0
5	0	0	0	1	1	0

```

public class GraphAdjMatrix extends Graph {
    private int[][] adjMatrix;

    public void implementAddEdge(int v, int w) {
        adjMatrix[v][w] = 1;
    }

    public void implementAddVertex() {
        int v = getNumVertices();
        if (v >= adjMatrix.length) {
            int[][] newAdjMatrix = new int[v * 2][v * 2];
            for (int i = 0; i < adjMatrix.length; i++) {
                for (int j = 0; j < adjMatrix.length; j++) {
                    newAdjMatrix[i][j] = adjMatrix[i][j];
                }
            }
            adjMatrix = newAdjMatrix;
        }
    }
}
    
```

$v*2$ instead of $v+1$ to
amortize cost of adding
new vertices in the future.

expand the 2-d array

The grid (2-d array) is indexed by the vertices labels and stores information in a particular location based on whether these two vertices have an edge between them or not

How long does it take to test
whether there is an edge between
vertex v and vertex w in the graph?

$O(1)$

- Algebraic representation of graph structure.
- Fast to test for edges.
- Fast to add/remove edges.
- Slow to add/remove vertices.
- Requires a lot of memory. sparse

Graph Implementations

<https://www.youtube.com/watch?v=2guA5uMEmZQ>

Graph Representation: Adjacency List

Motivation for new representation:

- want to avoid storing information on edges that aren't in the graph
- Edges connect a vertex to its neighbors

Neighbour can be reached by one hop

0 → {1}

1 → null

2 → {3}

3 → null

4 → {3}

5 → {3, 4}

- Easy to add vertices.
- Easy to add/remove edges.
- May use a lot less memory than adjacency matrices.

- Sparse graph: $O(1)$ edges for each vertex
- most applications use sparse graphs

Is it also fast?

```
public class GraphAdjList extends Graph {  
    private Map<Integer, ArrayList<Integer>> adjListsMap;  
    vertex → {neighbors}  
  
    public void implementAddVertex() {  
        int v = getNumVertices();  
        ArrayList<Integer> neighbors = new ArrayList<Integer>();  
        adjListsMap.put(v, neighbors);  
    }  
  
    public void implementAddEdge(int v, int w) {  
        adjListsMap.get(v).add(w);  
    }  
}
```

```
public class ArrayList<E>  
    extends AbstractList<E>  
    implements List<E>, RandomAccess, Cloneable, Serializable  
  
    Resizable-array implementation of the List interface. Implements all optional  
    list operations, and permits all elements, including null. In addition to  
    implementing the List interface, this class provides methods to manipulate  
    the size of the array that is used internally to store the list. (This class is  
    roughly equivalent to Vector, except that it is unsynchronized.)
```

The size, isEmpty, get, set, iterator, and listIterator operations run in constant time. The add operation runs in *amortized constant time*, that is, adding n elements requires $O(n)$ time. All of the other operations run in linear time (roughly speaking). The constant factor is low compared to that for the

Yes. Operations are all $O(1)$

Some Practices

How much storage is required to represent a graph as a **matrix**? (Big-O, Tightest Bound)

- A. $|V|$
- B. $|E|$
- C. $|V|+|E|$
- D. $|V|^2$**
- E. $|E|^2$

	0	1	2	3	4	5	6
0	0	0	0	1	0	0	0
1	0	0	1	0	0	0	0
2	1	0	0	0	0	0	0
3	0	0	0	0	1	0	0
4	0	0	0	0	0	0	0
5	0	0	0	0	1	0	0
6	0	0	0	0	1	1	0

What would change if undirected?

Symmetric matrix, hence half of the matrix is redundant, but still $O(|V|^2)$

For dense graphs with lots of edges, $|E|$ will be as large as $|V|^2$

$O(|V|)$

$O(|E|)$

0	→ {3}
1	→ {2}
2	→ {0}
3	→ {4}
4	→ null
5	→ {4}
6	→ {4, 5}

	0	1	2	3	4	5	6
0	0	0	1	1	0	0	0
1	0	0	1	0	0	0	0
2	1	1	0	0	0	0	0
3	1	0	0	0	1	0	0
4	0	0	0	1	0	1	1
5	0	0	0	0	1	0	1
6	0	0	0	0	1	1	0

Symmetric matrix

How much storage is required to represent a graph as an **adjacency list**? (Big-O, Tightest Bound)

- A. $|V|$
- B. $|E|$
- C. $|V|+|E|$**
- D. $|V|^2$
- E. $|E|^2$

Much more efficient for sparse graphs!

Find the Neighbors

count the number of occurrences in all lists

return the size of list

Neighbors: vertices that are adjacent.

there is edge in between

Out degree: number of outgoing edges.

In degree: number of incoming edges.

	0	1	2	3	4	5
0	0	1	0	0	0	0
1	0	0	0	0	0	0
2	0	0	0	1	0	0
3	0	0	0	0	0	0
4	0	0	0	1	0	0
5	0	0	0	1	1	0

count the number of nonzero slots

Which implementation makes finding the in degree more efficient?

Matrix: $O(|V|)$ **List:** $O(|E| + |V|)$

Which implementation makes finding the out degree more efficient?

Matrix: $O(|V|)$ **List:** $O(1)$

For dense graphs without multiple edges between pairs of vertices, $|E|$ is $O(|V|^2)$. so the adjacency matrix representation is faster. For sparse graphs, $|E| = O(|V|)$ so both representations have the same performance.

Coding getOutNeighbors (outgoing)

```
public class GraphAdjMatrix extends Graph {

    private int[][] adjMatrix;

    public List<Integer> getOutNeighbors(int v) {
        List<Integer> neighbors = new ArrayList<Integer>();
        for (int i = 0; i < getNumVertices(); i++) {
            for (int j = 0; j < adjMatrix[v][i]; j++)
                if (adjMatrix[v][i] > 0)
                    neighbors.add(i);
        }
        return neighbors;
    }
}
```

```
public class GraphAdjList extends Graph {

    private Map<Integer, ArrayList<Integer>> adjListsMap;

    public List<Integer> getOutNeighbors(int v) {
        return adjListsMap.get(v); // return v's list
        return new ArrayList<Integer>(adjListsMap.get(v)); // return a COPY of v's list
    }
}
```

Returning the array pointer allows the caller to modify the list contents. Not good encapsulation.

What does this change do?

- A. It's a change in the code but will not materially affect the output.
- ☒ B. It allows multiple edges between two vertices.
- C. It will have some other effect on the code behavior.

	0	1	2	3	4	5	6
0	0	0	0	2	0	0	0
1	0	0	1	0	0	0	0
2	1	0	0	0	0	0	0
3	0	0	0	0	1	0	0
4	0	0	0	0	0	0	0
5	0	0	0	0	1	0	0
6	0	0	0	0	1	1	0

0 → {3}

1 → {2}

2 → {0}

3 → {4}

4 → null

5 → {4}

6 → {4, 5}

Coding 2-Hop Neighbors (outgoing)

0 → {1, 2}

1 → {3}

2 → {1, 3}

3 → null

	0	1	2	3
0	0	1	1	0
1	0	0	0	1
2	0	1	0	1
3	0	0	0	0

Find all two-hop neighbors from given vertex

```
public class GraphAdjList extends Graph {  
  
    private Map<Integer, ArrayList<Integer>> adjListsMap;  
  
    public List<Integer> getDistance2 (int v) {  
        List<Integer> distance2 = new ArrayList<>();  
  
        // Loop through oneHop and get the neighbors of each  
        for(int u : getOutNeighbors(v)){  
            distance2.addAll(getOutNeighbors(u));  
        }  
        return distance2;  
    }  
}
```

```
public class GraphAdjMatrix extends Graph {  
  
    private int[][] adjMatrix;  
  
    public List<Integer> getDistance2 (int v) {  
        List<Integer> distance2 = new ArrayList<Integer>();  
  
        // Loop through oneHop and get the neighbors of each  
        for(int u : getOutNeighbors(v)){  
            distance2.addAll(getOutNeighbors(u));  
        }  
        return distance2;  
    }  
}
```

Coding 2-Hop Neighbors (Matrix Multiplication)

Matrix multiplication for finding two-hop neighbors

For all the vertices in the graph

$$\begin{pmatrix} 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}^2 = \text{matrix whose entries are two-hop neighbors!}$$

	0	1	2	3
0	0	1	1	0
1	0	0	0	1
2	0	1	0	1
3	0	0	0	0

$$\begin{pmatrix} 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} 0 & 1 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix} = \begin{pmatrix} \square & \square & \square & \square \\ \square & & & \end{pmatrix}$$

Node 3 is a two-hop neighbor of node 0 along two different paths

Dot product

$$0*0 + 1*0 + 1*0 + 0*0 = 0$$

$$0*0 + 1*1 + 1*1 + 0*0 = 2$$

$$0*1 + 1*0 + 1*1 + 0*0 = 1$$

$$0*0 + 0*0 + 0*0 + 1*0 = 0$$

$$0*1 + 1*0 + 1*0 + 0*0 = 0$$

	0	1	2	3
0	0	1	0	2
1	0	0	0	0
2	0	0	0	1
3	0	0	0	0

Matrix multiplication is well studied and optimized in software and hardware, and can be done very fast

Summary of Digraph Representations

In practice, Use adjacency-lists representation.

- Algorithms based on iterating over vertices adjacent from v .
- Real-world graphs tend to be **sparse** (not **dense**).

↑
proportional to V

↑
proportional to V^2

Two graphs ($V = 50$)

representation	space	insert edge from v to w	edge from v to w ?	iterate over vertices adjacent from v ?
adjacency matrix	V^2	1	1	V
adjacency lists	$E + V$	1	$\text{outdegree}(v)$	$\text{outdegree}(v)$

DFS

BFS

The diagram illustrates a tree structure with 10 nodes, representing a search space. The root node has three children. The left child has two children of its own, and the middle child has two children. The right child has one child. The leftmost child of the left child has one child. The middle child of the left child has one child. The rightmost child of the left child has one child. The rightmost child of the middle child has one child. The rightmost child of the right child has one child. The tree structure is identical for both DFS and BFS, but the search order is different. In DFS, the search starts at the root and goes down to the leftmost leaf node before backtracking. In BFS, the search starts at the root and visits all nodes level by level, starting from the root and moving to its children, then to the children of the children, and so on.

Represent Problems as Graphs: Maze Exploration

Goal. Explore every intersection in the maze.

Maze graph. Vertex = intersection. Edge = passage.

intersection

passage

Depth-First Search (DFS)

Goal. Systematically traverse a graph.

Typical applications.

- Find all vertices connected to a given source vertex.
- Find a path between two vertices.

Data structures.

- Boolean array `marked[]` to mark vertices.
- Integer array `edgeTo[]` to keep track of paths.
 - `(edgeTo[w] == v)` means that edge `v-w` taken to discover vertex `w`

DFS (to visit a vertex `v`)

Mark vertex `v`.

Recursively visit all unmarked vertices `w` adjacent to `v`.

Java execution stack is used to keep track of where to search next

<code>v</code>	<code>marked[]</code>	<code>edgeTo[]</code>

Depth-First Search: Java Implementation

```
public class DepthFirstPaths {
```

```
    private boolean[] marked;  
    private int[] edgeTo;  
    private int s;
```

← marked[v] = true if v connected to s
← edgeTo[v] = previous vertex on path from s to v

```
    public DepthFirstPaths(Graph G, int s) {  
        ...  
        dfs(G, s);  
    }
```

← initialize data structures
← find vertices connected to s

```
    private void dfs(Graph G, int v) {  
        marked[v] = true;  
        for (int w : G.adj(v))  
            if (!marked[w])  
            {  
                edgeTo[w] = v;  
                dfs(G, w);  
            }  
    }  
}
```

← recursive DFS does the work

- Code for directed graphs identical to undirected one.

Depth-First Search Application: Flood Fill

Problem. Flood fill is a flooding algorithm that determines and alters the area connected to a given node in a multi-dimensional array with some matching attribute.

Solution.

- Build a **grid graph**.
- Vertex: pixel.
- Edge: between two adjacent gray pixels.
- Blob: all pixels connected to given pixel.

Reachability Application: Mark–Sweep Garbage Collector

Every data structure is a digraph.

- Vertex = object.
- Edge = reference.
- Roots: Objects known to be directly accessible by program (e.g., stack).
- **Reachable objects**: Objects indirectly accessible by program (starting at a root and following a chain of pointers).

Mark–sweep algorithm. [McCarthy, 1960]

Mark: mark all reachable objects.

Sweep: if object is unmarked, it is garbage (so add to free list).

Memory cost. Uses 1 extra mark bit per object (plus DFS stack).

Recall from Lecture 2-classes and objects in java

```
public class Location
```

```
{
```

```
// Code omitted here
```

```
public static void main(String[] args)
```

```
{
```

```
    Location loc1 = new Location(40.7, -73.6);
```

```
    Location loc2 = new Location(51.7, -1.2);
```

```
    loc1 = loc2;
```

```
    loc1.latitude = 35.2;
```

```
    System.out.println(loc2.latitude + ", " + loc2.longitude);
```

After assignment `loc1 = loc2`, the Object `Location(40.7, -73.6)` is unreachable and should be garbage-collected.

\$ 35.2, -1.2

Breadth-First Search (BFS)

BFS (from source vertex s)

Put s onto a FIFO queue, and mark s as visited.

Repeat until the queue is empty:

- remove the least recently added vertex v
- add each of v 's unmarked neighbors to the queue, and mark them.

Queue

4
3
5
1
2
0

v	marked[]	edgeTo[]	distTo[]	
0	T	—	0	←
1	T	0	1	←
2	T	0	1	←
3	T	2	2	←
4	T	2	2	←
5	T	0	1	←

$\text{distTo}[v] = \text{distTo}[\text{edgeTo}[v]] + 1;$

$s.\text{distTo}[v]$ stores the distance from s to v

Breadth-First Search: Java Implementation

```
public class BreadthFirstPaths {  
    private boolean[] marked;  
    private int[] edgeTo;  
    private int[] distTo;  
    ...  
    private void bfs(Graph G, int s) {  
        Queue<Integer> q = new Queue<Integer>();  
        q.enqueue(s);  
        marked[s] = true;  
        distTo[s] = 0;  
  
        while (!q.isEmpty()) {  
            int v = q.dequeue();  
            for (int w : G.adj(v)) {  
                if (!marked[w]) {  
                    q.enqueue(w);  
                    marked[w] = true;  
                    edgeTo[w] = v;  
                    distTo[w] = distTo[v] + 1;  
                }  
            }  
        }  
    }  
}
```

- **DFS**. Put unvisited vertices on a **stack**.
- **BFS**. Put unvisited vertices on a **queue**.

← initialize FIFO queue of
vertices to explore

← found new vertex w via edge v-w

Every **undirected** graph is a **digraph** (with edges in both directions).

- Code for directed graphs identical to undirected one.
- Function `G.adj(v)` returns all neighbors in the edge arrow direction.

Breadth-First Search Properties

level-order

Proposition. BFS examines vertices in increasing distance (number of edges) from s .

Proposition. In any connected graph, BFS computes shortest paths (fewest number of edges) from s to all other vertices in time proportional to $E + V$.

Pf. [correctness] Queue always consists of zero or more vertices of distance k from s , followed by zero or more vertices of distance $k + 1$.

Pf. [running time] Each vertex connected to s is visited once, and all its edges are checked.

Breadth-First Search Application: Web Crawler

Goal. Crawl web, starting from some root web page, say www.hofstra.edu.

Solution. [BFS with implicit digraph]

- Choose root web page as source s .
- Maintain a Queue of websites to explore.
- Maintain a SET of marked websites.
- Dequeue the next website and enqueue any unmarked websites to which it links.

Multiple-Source Shortest Paths Problem

Given a digraph and a **set** of source vertices, find shortest path from any vertex in the set to each other vertex, assuming all edges have weight 1.

Ex. $S = \{1, 7, 10\}$.

- Shortest path to 4 is $7 \rightarrow 6 \rightarrow 4$.
- Shortest path to 5 is $7 \rightarrow 6 \rightarrow 0 \rightarrow 5$.
- Shortest path to 12 is $10 \rightarrow 12$.
- ...

How to implement multi-source shortest paths algorithm?

Use **BFS**, but initialize by enqueueing all source vertices.

Connectivity Queries Problem

- Vertices v and w are **connected** if there is a path between them.
- In **undirected graph**, the relation "is connected to" is an **equivalence** relation:
 - Reflexive: v is connected to v .
 - Symmetric: if v is connected to w , then w is connected to v .
 - Transitive: if v connected to w and w connected to x , then v connected to x .
- Goal.** Preprocess **undirected** graph to answer queries of the form *is v connected to w ?* in **constant time** while using adjacency list.
- A **connected component** is a maximal set of connected vertices.
- Given connected components, can answer queries in **constant time**.

Can also use BFS

Connected Components Application: Particle Detection

Given grayscale image of particles, identify "blobs."

- Vertex: pixel.
- Edge: between two adjacent pixels with grayscale value > 70 .
- Blob: connected component of 20-30 pixels.

black = 0
white = 255

Particle tracking. Track moving particles over time.

Precedence Scheduling Problem

Goal. Given a set of tasks to be completed with precedence constraints, in which order should we schedule the tasks?

Digraph model. vertex = task; edge = precedence constraint.

tasks

precedence constraint graph

feasible schedule

Topological sort. Redraw DAG(Directed **acyclic** graph) so all edges point upwards.

Graph traversal with DFS: pre-order, post-order

```
function preOrderTraversal(node) {  
  if (node !== null) {  
    visitNode(node);  
    preOrderTraversal(node.left);  
    preOrderTraversal(node.right);  
  }  
}
```

```
function postOrderTraversal(node) {  
  if (node !== null) {  
    postOrderTraversal(node.left);  
    postOrderTraversal(node.right);  
    visitNode(node);  
  }  
}
```

Recall: Binary Tree traversal with DFS: pre-order, post-order

```
function preOrderTraversal(node) {  
  if (node !== null) {  
    visitNode(node);  
    foreach(c ∈ node.children) {  
      preOrderTraversal(c);  
    }  
  }  
}
```

```
function postOrderTraversal(node) {  
  if (node !== null) {  
    foreach(c ∈ node.children) {  
      postOrderTraversal(c);  
    }  
    visitNode(node);  
  }  
}
```

Graph traversal with DFS: pre-order, post-order

Topological Sort

- topological sort for Directed Acyclic Graph (DAG) is a linear ordering of vertices such that for every directed edge $u \rightarrow v$, vertex u comes before v in the ordering, i.e., all pair-wise precedence constraints are satisfied.

The first vertex in topological sort is always a vertex with an in-degree of 0 (a vertex with no incoming edges), i.e., 4 or 5. Possible topological sorts include “5 4 2 3 1 0”, “4 5 2 3 1 0”, “4 5 0 2 3 1”, “5 2 3 4 1 0”, etc.

How to get dressed

Multiple Topological ordering for a graph

Some of possible topological ordering

Multiple Topological ordering for a graph

Topological Sort Applications

- Task scheduling and project management.
- Dependency resolution in package management systems.
- Determining the order of compilation in software build systems with Makefile
- Deadlock detection in operating systems.
- Course scheduling in universities.

Topological Sort Details

Java execution stack

- Run depth-first search
- Return vertices in **reverse postorder**.

not a reachability problem

done
```

Example 1: Topological Sort

- Starting from node A:
- Pre-order traversal is “A B F I J K E C G D H”.
- Post-order traversal is “I K J F E B G C H D A”.
- A topological sort is reverse order of Post-order traversal: “A D H C G B E F J K I”.
- Starting from a different node will give you a different topological sort, but all of them must start with A, since it must precede all the other nodes based on the DAG.
- Any post-order traversal must visit A last, since all of A’s neighbors must be visited before visiting A.

Topological Sort Visualized and Explained

<https://www.youtube.com/watch?v=7J3GadLzydI>

Example 2: Topological Sort

- Starting from node 5:
 - Pre-order traversal is “5 2 3 1 0 4”.
 - Post-order traversal is “1 3 2 0 5 4”.
 - A topological sort is reverse order of Post-order traversal: “4 5 0 2 3 1”.
- Starting from node 4:
 - Pre-order traversal is “4 0 1 5 2 3”
 - Post-order traversal is “0 1 4 3 2 5”.
 - Another topological sort is reverse order of Post-order traversal: “5 2 3 4 1 0”.
- Starting from node 0:
 - Pre-order traversal is “0 5 2 3 1 4”
 - Post-order traversal is “0 1 3 2 5 4”.
 - Another topological sort is reverse order of Post-order traversal: “4 5 2 3 0”.
- You may try starting any other node.

Cycles and undirected edges

- Why is topological sort not possible for graphs having cycles?
 - Imagine a graph with 3 vertices and edges = $\{1 \text{ to } 2, 2 \text{ to } 3, 3 \text{ to } 1\}$ forming a cycle. Now if we try to topologically sort this graph starting from any vertex, it will always create a contradiction to our definition. All the vertices in a cycle are indirectly dependent on each other hence topological sort fails.
- Why is topological sort not possible for graphs with undirected edges?
 - Special case of a cycle. Undirected edge between two vertices u and v means, there is an edge from u to v as well as from v to u . Because of this both the nodes u and v depend upon each other and none of them can appear before the other in the topological sort without creating a contradiction.

Topological Sort: Java Implementation

```
public class DepthFirstOrder {
    private boolean[] marked;
    private Stack<Integer> reversePostorder;

    public DepthFirstOrder(Digraph G) {
        reversePostorder = new Stack<Integer>();
        marked = new boolean[G.V()];
        for (int v = 0; v < G.V(); v++)
            if (!marked[v]) dfs(G, v);
    }

    private void dfs(Digraph G, int v) {
        marked[v] = true;
        for (int w : G.adj(v))
            if (!marked[w]) dfs(G, w);
        reversePostorder.push(v);
    }

    public Iterable<Integer> reversePostorder()
    { return reversePostorder; }
}
```

returns all vertices in
"reverse DFS postorder"

Proposition. A digraph has a topological sort iff no directed cycle.

Pf.

- If directed cycle, topological sort impossible.
- If no directed cycle, DFS-based algorithm finds a topological sort.

a digraph with a directed cycle

Goal. Given a digraph, find a directed cycle.

Solution. DFS. See next slide.

Directed Cycle Detection

- Run depth-first search from every unmarked vertex.
- Keep track of vertices currently in recursion stack of function for DFS traversal with `onStack[]` array.
- If we reach a vertex that is already in the recursion stack, then we found a **cycle** in the tree, and we're done
- Retrieve the cycle using `edgeTo[]` array.

- set `onStack[v]` to T when `dfs(v)` is called
- set `onStack[v]` to F when `dfs(v)` returns

The other cycle can be detected when node 6 is visited

v	marked[]	onStack[]	edgeTo[]
0	T	T	—
1	T	T	0
2	T	T	0
3	T	T	2
4	T	T	1
5	T	T	3
6	F	F	—

stack top

2 3 5 2

Java execution stack

```
dfs(0)
  dfs(1)
    dfs(4)
      4 done
    1 done
  dfs(2)
    dfs(3)
      check 4
    dfs(5)
      check 2
    done
```

- Vertex 2 is marked and onStack
- Found the cycle
- Save the cycle using `edgeTo[]` to a stack

<https://favtutor.com/blogs/detect-cycle-in-directed-graph>

Directed Cycle Detection Application: Cyclic Inheritance

The Java compiler does cycle detection.

```
public class A extends B
{
    ...
}
```

```
public class B extends C
{
    ...
}
```

```
public class C extends A
{
    ...
}
```

```
%javac A.java
A.java:1: cyclic inheritance
involving A
public class A extends B { }
                ^
1 error
```

Directed Cycle Detection Application: Spreadsheet Recalculation

Microsoft Excel does cycle detection.

Kahn's algorithm for Topological Sort

- The algorithm works by repeatedly finding vertices with no incoming edges, removing them from the graph, and updating the incoming edges of the remaining vertices. This process continues until all vertices have been ordered.
 - Add all nodes with in-degree 0 to a queue.
 - While the queue is not empty:
 - Remove a node from the queue.
 - For each outgoing edge from the removed node, decrement the in-degree of the destination node by 1.
 - If the in-degree of a destination node becomes 0, add it to the queue.
 - If the queue is empty and there are still nodes in the graph, the graph contains a cycle and cannot be topologically sorted.
 - The nodes in the queue represent the topological sort of the graph.
- Time Complexity: $O(V+E)$.
 - The outer for loop will be executed V number of times and the inner for loop will be executed E number of times.

Quiz 1

- Write out the adjacency matrix and adjacency list for the directed graph.

Adjacency Matrix

	A	B	C	D	E	F	G	To
A		✓		✓				
B			✓					
C						✓		
D		✓			✓	✓		
E						✓		
F								
G						✓		

From

Adjacency List

Quiz 2

- Write out the adjacency matrix and adjacency list for the undirected graph.

Adjacency Matrix

	A	B	C	D	E	F	G
A		✓		✓			
B	✓		✓	✓			
C		✓				✓	
D	✓	✓			✓	✓	
E				✓		✓	
F			✓	✓	✓		✓
G						✓	

Adjacency List

A	→	B, D
B	→	A, C, D
C	→	B, F
D	→	A, B, E, F
E	→	D, F
F	→	C, D, E, G
G	→	F

Quiz 3: Pre-Order & Post-Order Traversals

DFS Pre-Order:

DFS Post-Order:

Stack:

We use a stack-based implementation instead of recursive function calls as shown in [Slide 35 Topological Sort Details](#)

Stack: A

DFS Pre-Order:

A

DFS Post-Order:

Stack: A, B

DFS Pre-Order:

A, B

DFS Post-Order:

Stack: A, B, C

DFS Pre-Order:

A, B, C

DFS Post-Order:

Stack: A, B, C, F

DFS Pre-Order:

A, B, C, F

DFS Post-Order:

Stack: A, B, C

DFS Pre-Order:
A, B, C, F

DFS Post-Order:
F

Stack: A, B

DFS Pre-Order:

A, B, C, F

DFS Post-Order:

F, C

Stack: A

DFS Pre-Order:

A, B, C, F

DFS Post-Order:

F, C, B

Stack: A, D

DFS Pre-Order:

A, B, C, F, D

DFS Post-Order:

F, C, B

Stack: A, D, E

DFS Pre-Order:

A, B, C, F, D, E

DFS Post-Order:

F, C, B,

Stack: A, D

DFS Pre-Order:

A, B, C, F, D, E

DFS Post-Order:

F, C, B, E

Stack: A,

DFS Pre-Order:

A, B, C, F, D, E

DFS Post-Order:

F, C, B, E, D

Stack:

DFS Pre-Order:

A, B, C, F, D, E

DFS Post-Order:

F, C, B, E, D, A

Stack:

DFS Pre-Order:
A, B, C, F, D, E, G

DFS Post-Order:
F, C, B, E, D, A, G

Topological Sort (reverse of DFS
Post-Order):
G, A, D, E, B, C, F

* if we allow DFS to restart on unmarked nodes, G would be added to the stack (and ultimately the last element in both the preorder and postorder traversals)

Quiz 4: BFS

BFS:

Queue: A

BFS:
A

Queue: B D

BFS:
A B

Queue: D C

BFS:
A B D

Queue: C E F

BFS:
A B D C

Queue: E F

BFS:
A B D C E

Queue: F

BFS:
A B D C E F

Queue:

BFS:
A B D C E F

Queue: G

BFS:
A B D C E F G

Queue:
