# L3.1 L3.1 Convolutional Neural Networks

Zonghua Gu, Umeå University

Nov. 2023

# Outline

---

- CNN Convolution layers
- Pooling and Fully-Connected layers
- Well-known CNN architectures

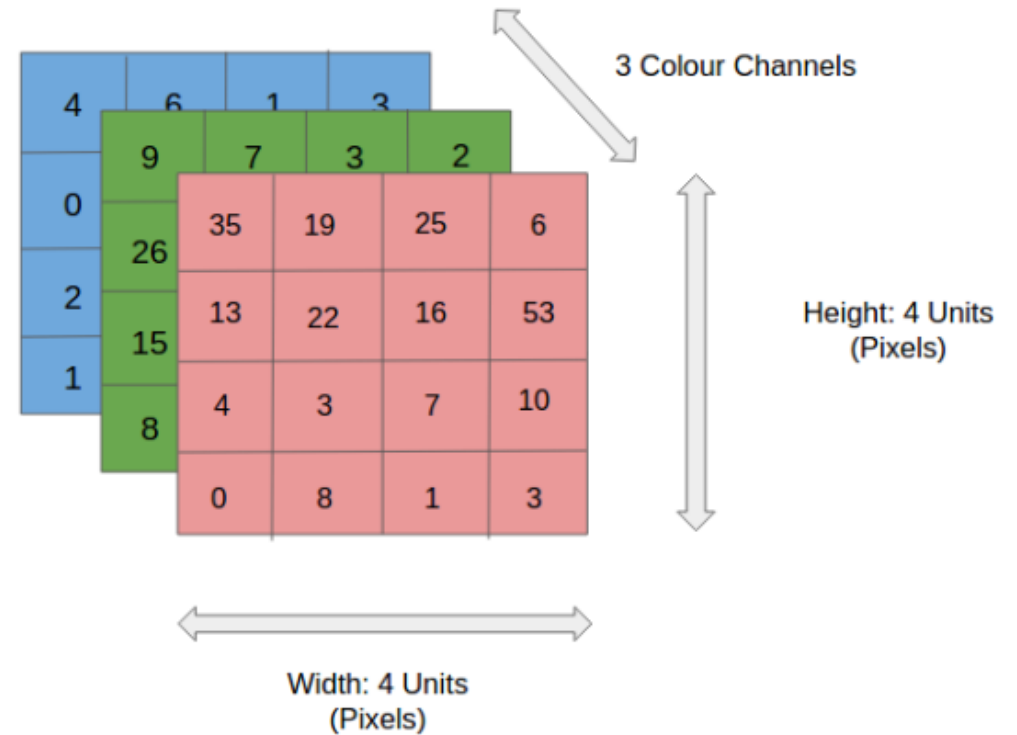

# Classic Computer Vision

- Most “classic” (non-ML) CV algorithms are implemented in the OpenCV library, including
  - Core Operations:
    - basic operations on image like pixel editing, geometric transformations...
  - Image Processing
    - Thresholding, smoothing, edge detection, Hough Line Transform...
  - Feature Detection and Description
    - HOG, SIFT, SURF, BRIEF, ORB...
  - Video analysis
    - Object tracking w. optical flow
  - Camera Calibration and 3D Reconstruction
- They are simple, fast and reliable (e.g., for lane detection), and are often used in place of or in conjunction w. complex ML/DL algorithms, which may sometimes be unreliable and unpredictable

# Input Image Encoding

- A size  $N \times N$  color image has volume  $N \times N \times 3$ , w.  $N \times N$  pixels and 3 color components (Red, Green, and Blue, RGB) for each pixel
- A size  $N \times N$  greyscale image has volume  $N \times N \times 1$
- Color depth, or bit depth, is number of bits used for each color component of a single pixel
  - Typical value is 8, so pixel value has range  $[0, 255]$
  - Larger depth is possible, e.g., true color (24-bit) is used in computer and phone displays for human eyes, but 8-bit is typically enough for CV tasks

# Filters/Kernels in Computer Vision

- **Convolution** operation: we slide each **filter** (also called **kernel**) across the width and height of the input volume, and compute dot products between the entries of the filter and the input. As the filter slides over the width and height of the input volume, a 2D **activation map** (also called **activation map**) is produced that gives the responses of that filter at every spatial position.
  - Dot product: elementwise multiplication of a filter w. corresponding input values, then summing them to generate one output value
- Filters extract features used by downstream tasks such as classification, image segmentation, etc.

# Common Filters in CV

- These filters were designed, or “hand-crafted”, by human experts

Operation	Kernel $w$	Image result $g(x,y)$			
Identity	$\begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}$		Box blur (normalized)	$\frac{1}{9} \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}$	
Edge detection	$\begin{bmatrix} 1 & 0 & -1 \\ 0 & 0 & 0 \\ -1 & 0 & 1 \end{bmatrix}$		Gaussian blur 3 × 3 (approximation)	$\frac{1}{16} \begin{bmatrix} 1 & 2 & 1 \\ 2 & 4 & 2 \\ 1 & 2 & 1 \end{bmatrix}$	
	$\begin{bmatrix} 0 & -1 & 0 \\ -1 & 4 & -1 \\ 0 & -1 & 0 \end{bmatrix}$		Gaussian blur 5 × 5 (approximation)	$\frac{1}{256} \begin{bmatrix} 1 & 4 & 6 & 4 & 1 \\ 4 & 16 & 24 & 16 & 4 \\ 6 & 24 & 36 & 24 & 6 \\ 4 & 16 & 24 & 16 & 4 \\ 1 & 4 & 6 & 4 & 1 \end{bmatrix}$	
	$\begin{bmatrix} -1 & -1 & -1 \\ -1 & 8 & -1 \\ -1 & -1 & -1 \end{bmatrix}$		Unsharp masking 5 × 5 Based on Gaussian blur with amount as 1 and threshold as 0 (with no image mask)	$\frac{-1}{256} \begin{bmatrix} 1 & 4 & 6 & 4 & 1 \\ 4 & 16 & 24 & 16 & 4 \\ 6 & 24 & -476 & 24 & 6 \\ 4 & 16 & 24 & 16 & 4 \\ 1 & 4 & 6 & 4 & 1 \end{bmatrix}$	
Sharpen	$\begin{bmatrix} 0 & -1 & 0 \\ -1 & 5 & -1 \\ 0 & -1 & 0 \end{bmatrix}$				

# Machine Learning Meets CV

- Instead of hand-crafted filters in classic CV, why not learn custom filters from data by supervised learning?
  - For easy tasks like edge detection, learning may recover filters similar to hand-crafted ones.
  - For difficult tasks like cat vs. dog classification, learning is essential to achieving good results

The diagram illustrates a 2D convolution operation. It shows a 6x6 input grid (represented by empty cells) being convolved with a 3x3 kernel (represented by a grid of weights  $w_1$  through  $w_9$ ). The result is a 4x4 output grid (represented by empty cells). The operation is denoted by an asterisk (\*) and an equals sign (=).

# Convolutional Neural Network (CNN)

- Since the Deep Learning revolution that started a decade ago, Deep Neural Networks (DNNs) are widely deployed in many application domains
  - Multiple hidden layers of a DNN extract a hierarchy of increasingly-abstract features layer-by-layer, until the last layer produces a classification result
- A CNN, or ConvNet, consists of a sequence of Convolutional (CONV) Layers, Pooling (POOL) Layers and non-linear activation functions for feature extraction, followed by one or more Fully-Connected (FC) Layers for classification based on the extracted features

Feature visualization of convolutional net trained on ImageNet from [Zeiler & Fergus 2013]

# Receptive Field and Parameter Sharing

- Each neuron in a CONV layer has local, sparse connectivity to a small patch of the input volume w. size of the filter, called its Receptive Field (e.g., 3x3, 5x5, etc.)
  - Each neuron covers a limited, narrow “field-of-view”
  - In contrast, each neuron in a FC layer has RF that covers the entire input volume
- Parameter sharing: all neurons in the same CONV layer share the same filter params  $w$ ,  $b$ 
  - It helps to reduce the number of params significantly compared to fully-connected networks
  - It gives translation invariance, e.g., an edge can be detected regardless of its location in the image

A filter sliding across different parts of the image

# Convolution Operation

- A filter slides over the image spatially, computing dot products  $w^T x + b$  to generate an activation map (or feature map) as output
- Input may be an input RGB image w. 3 channels, hence depth=3, or intermediate activation maps generated by hidden layers of a CNN. We use the terms “input volume” and “output volume” to emphasize they may be 3D tensors
- At each sliding position, the output is a scalar number, computed by taking a dot product  $w x + b$  between the  $5 \times 5 \times 3$  filter with weights  $w$ , bias  $b$ , and a  $5 \times 5 \times 3$  image patch  $x$ , with  $5 * 5 * 3 = 75$  multiply operations and one addition of the bias

# Convolution Operation

# Stacked activation maps

- If we have six  $5 \times 5$  filters, we'll get six different activation maps, each computed by convolution of one filter with the input
  - For each  $5 \times 5$  patch of the input, there are 6 different neurons looking at it, each extracting different features
- We stack these up to get an output volume (a new "image") of size  $28 \times 28 \times 6$ , an intermediate representation to be passed to subsequent layers

→  
Convolution Layer w.  
six  $5 \times 5$  filters

# Concrete Example w. 3 Filters

- 3 filters  $W_0, W_1, W_2$ , each extracting different features. ( $W_i * X_j$  denotes convolution of filter  $W_i$  w. input  $X_j$ ) (bias terms are assumed to be 0 here)
- Upper left: filter  $W_0$  extracts vertical line features  $Z_0$  from input image  $X_1$ . (the other 2 filters do not extract any meaningful features)
- Lower left: filter  $W_1$  extracts horizontal line features  $Z_1$  from input image  $X_2$  (the other 2 filters do not extract any meaningful features)

$$Z_0 = W_0 * X_1 + b_0$$

# Convolution Operation Summary

1 filter/kernel, 1 output activation map

3 filters/kernels, 3 output activation maps

# Convolution of a Filter on RGB Image w. 3 Channels

- 6x6 input feature map w. 3 channels; one 3x3 filter with depth 3; 4x4 output feature map w. one channel
- # channels of input feature map == # depth of each filter (3)
- # channels of output feature map == # filters (1)

# Convolution of 2 Filters on RGB Image w. 3 Channels

- 6x6 input feature map w. 3 channels; two 3x3 filters with depth 3; 4x4 output feature map w. two channels
- # channels of input feature map == # depth of each filter (3)
- # channels of output feature map == # filters (2)

# Convolution Example 1 in PyTorch

- `conv=nn.Conv2d(in_channels=2, out_channels=1, kernel_size=3)`
  - A CONV layer with an input image with 2 channels (`in_channels=2`), 1  $3 \times 3$  filter (with depth 2), 1 output activation maps (`out_channels=1`).
  - (Bias terms are assumed to be 0)

# Convolution Example 2 in PyTorch

- `conv4=nn.Conv2d(in_channels=2, out_channels=3, kernel_size=3)`
  - Pytorch code for a CONV layer with an input image with 2 channels (in\_channels=2), 3  $3 \times 3$  filters (with depth 2), 3 output activation maps (out\_channels=3)
  - (Bias terms are assumed to be 0)

Three 3 × 3 filters

# Convolution Example 2: Output

- Each of the three filters convolved with the input image generates an output activation map.
- The output volume consists of three  $3 \times 3$  activation maps, with volume  $3 \times 3 \times 3$

$$\begin{aligned}
 (Z)_0 &= \begin{matrix} W_{0,0} \\ \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0.5 & 0 \\ 0 & 0 & 0 \end{bmatrix} \end{matrix} * \begin{matrix} (X)_0 \\ \begin{bmatrix} 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 & 1 \end{bmatrix} \end{matrix} + \begin{matrix} W_{0,1} \\ \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0.5 & 0 \\ 0 & 0 & 0 \end{bmatrix} \end{matrix} * \begin{matrix} (X)_1 \\ \begin{bmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \end{matrix} \\

# Computation of CONV Layer Sizes

**Summary.** To summarize, the Conv Layer:

- Accepts a volume of size  $W_1 \times H_1 \times D_1$
- Requires four hyperparameters:
  - Number of filters  $K$ ,
  - their spatial extent  $F$ ,
  - the stride  $S$ ,
  - the amount of zero padding  $P$ .
- Produces a volume of size  $W_2 \times H_2 \times D_2$  where:
  - $W_2 = (W_1 - F + 2P)/S + 1$
  - $H_2 = (H_1 - F + 2P)/S + 1$  (i.e. width and height are computed equally by symmetry)
  - $D_2 = K$
- With parameter sharing, it introduces  $F \cdot F \cdot D_1$  weights per filter, for a total of  $(F \cdot F \cdot D_1) \cdot K$  weights and  $K$  biases.
- In the output volume, the  $d$ -th depth slice (of size  $W_2 \times H_2$ ) is the result of performing a valid convolution of the  $d$ -th filter over the input volume with a stride of  $S$ , and then offset by  $d$ -th bias.

Common settings:  
 $K =$  (powers of 2, e.g. 32, 64, 128, 512)  
-  $F = 3, S = 1, P = 1$   
-  $F = 5, S = 1, P = 2$   
-  $F = 1, S = 1, P = 0$

- Recall: Each filter has the same depth  $D_1$  as its input volume, and the number of filters  $K$  equals the depth  $D_2$  of its output volume
- In practice, it is common to have stride  $S = 1$ , filter size  $F \times F$ , and zero-pad  $P = \frac{1}{2}(F - 1)$ . Then output activation map has same spatial size as input. This is called “same padding”
  - $W_2 = \frac{1}{S}(W_1 + 2P - F) + 1 = \frac{1}{1}(W_1 + F - 1 - F) + 1 = W_1$ ; similarly,  $H_2 = H_1$
  - e.g.,  $F < 3 \Rightarrow P = 0$ ;  $F = 3 \Rightarrow P = 1$ ;  $F = 5 \Rightarrow P = 2$

# CONV Example 1: No Padding

- Input volume:  $5 \times 5 \times 1$  ( $W_1 = H_1 = N_1 = 32, D_1 = 1$ )(e.g., a greyscale image)
- A  $3 \times 3 \times 1$  filter  $\begin{bmatrix} 1 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 1 \end{bmatrix}$  ( $K = 1, F = 3$ )  
w. stride  $S = 1$ , no pad
- Output activation map:
  - Spatial size:  $W_2 = H_2 = N_2 = \frac{1}{S}(N_1 + 2P - F) + 1 = \frac{1}{1}(5 - 3) + 1 = 3$
  - Depth:  $D_2 = K = 1$
- Output volume:  $3 \times 3 \times 1$
- Even though the fig shows sequential computation, convolution operations are inherently parallel, hence suitable for efficient implementation on parallel hardware like GPUs

- Input volume:  $M \times N \times 3$
- A  $3 \times 3 \times 3$  filter ( $K = 1, F = 3$ ) w. stride  $S = 1$ , pad  $P = 1$
- Output volume:  $M \times N \times 1$  (since  $\frac{1}{1}(M + 2 * 1 - 3) + 1 = M$ ,  
 $\frac{1}{1}(N + 2 * 1 - 3) + 1 = N$ )

# CONV Example 5: Multiple Filters $K = 10$

- Input volume:  $32 \times 32 \times 3$  ( $W_1 = H_1 = N_1 = 32, D_1 = 3$ )
- 10  $5 \times 5 \times 3$  filters ( $K = 10, F = 5$ ) w. stride  $S = 1$ , no pad ( $P = 0$ )
- Each output activation map:
  - Spatial size:  $W_2 = H_2 = N_2 = \frac{1}{S}(N_1 + 2P - F) + 1 = \frac{1}{1}(32 - 5) + 1 = 28$
  - Depth:  $D_2 = K = 10$
- Output volume:  $28 \times 28 \times 10$
- No. params (weights and biases) in this layer: each filter has  $5 * 5 * 3 + 1 = 76$  params, so 10 filters add up to  $76 * 10 = 760$  params

# CONV Example 6: Pad $P = 2$

- Input volume:  $32 \times 32 \times 3$  ( $W_1 = H_1 = N_1 = 32, D_1 = 3$ )
- $10 \ 5 \times 5 \times 3$  filters ( $K = 10, F = 5$ ) w. stride  $S = 1$ , pad  $P = 2$
- Each activation map:
  - Spatial size:  $W_2 = H_2 = N_2 = \frac{1}{S}(N_1 + 2P - F) + 1 = \frac{1}{1}(32 + 2 * 2 - 5) + 1 = 32$
  - Depth:  $D_2 = K = 10$
- Output volume:  $32 \times 32 \times 10$
- No. params: each filter has  $5 * 5 * 3 + 1 = 76$  params, so 10 filters add up to  $76 * 10 = 760$  params

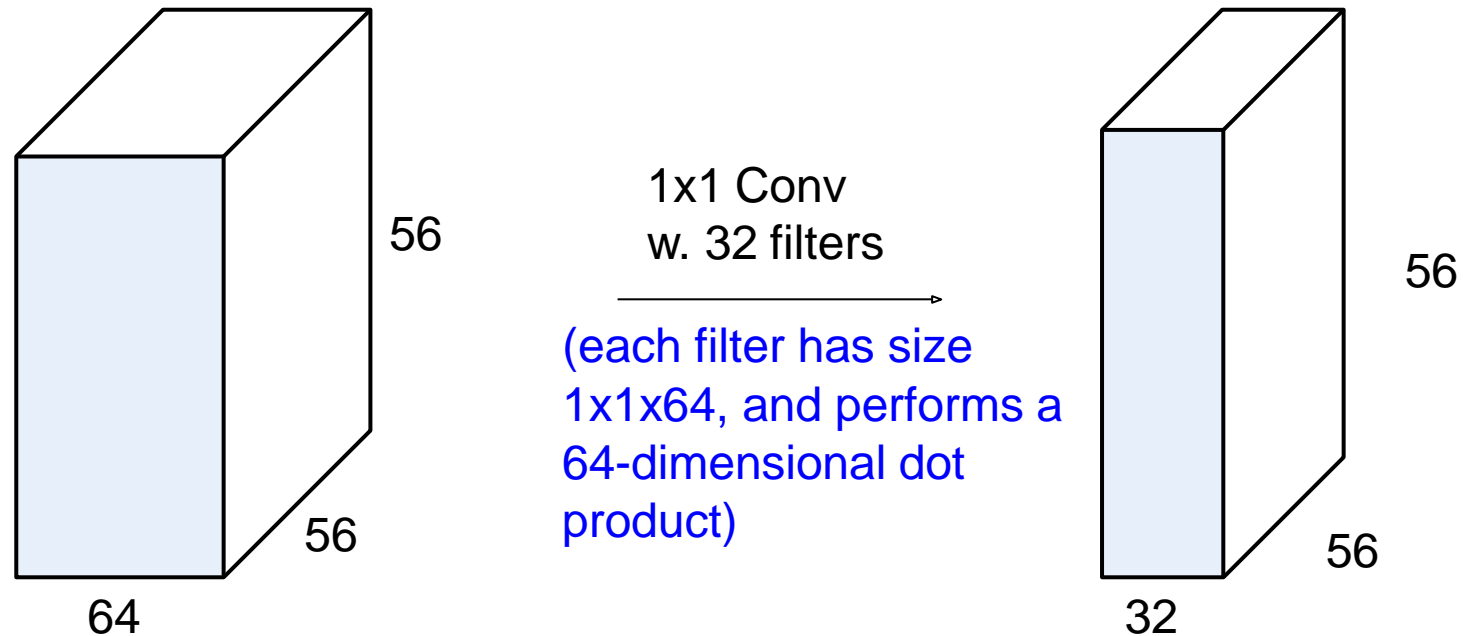

# Pointwise Convolution with $1 \times 1$ Filter

- A  $1 \times 1$  filter performs “mixing” of the input channels, then applies a non-linear activation function
- Can be used to reduce the number of channels (volume depth); the non-linear activation function also helps increase model capacity

# 1 × 1 Filter Example

- Input volume:  $56 \times 56 \times 64$  ( $W_1 = H_1 = N_1 = 56, D_1 = 64$ )
- 32  $1 \times 1 \times 64$  filters ( $K = 32, F = 1$ ) w. stride  $S = 1$ , no pad
- Each activation map:
  - Spatial size:  $W_2 = H_2 = N_2 = \frac{1}{S}(N_1 + 2P - F) + 1 = \frac{1}{1}(56 - 1) + 1 = 56$
  - Depth:  $D_2 = K = 32$
- Output volume:  $56 \times 56 \times 32$
- No. params: each filter has  $1 * 1 * 64 + 1 = 65$  params, so 32 filters add up to  $65 * 32 = 2080$  params

# Dilated Convolution

- Insert 0s between input elements to increase receptive field size without increasing # params

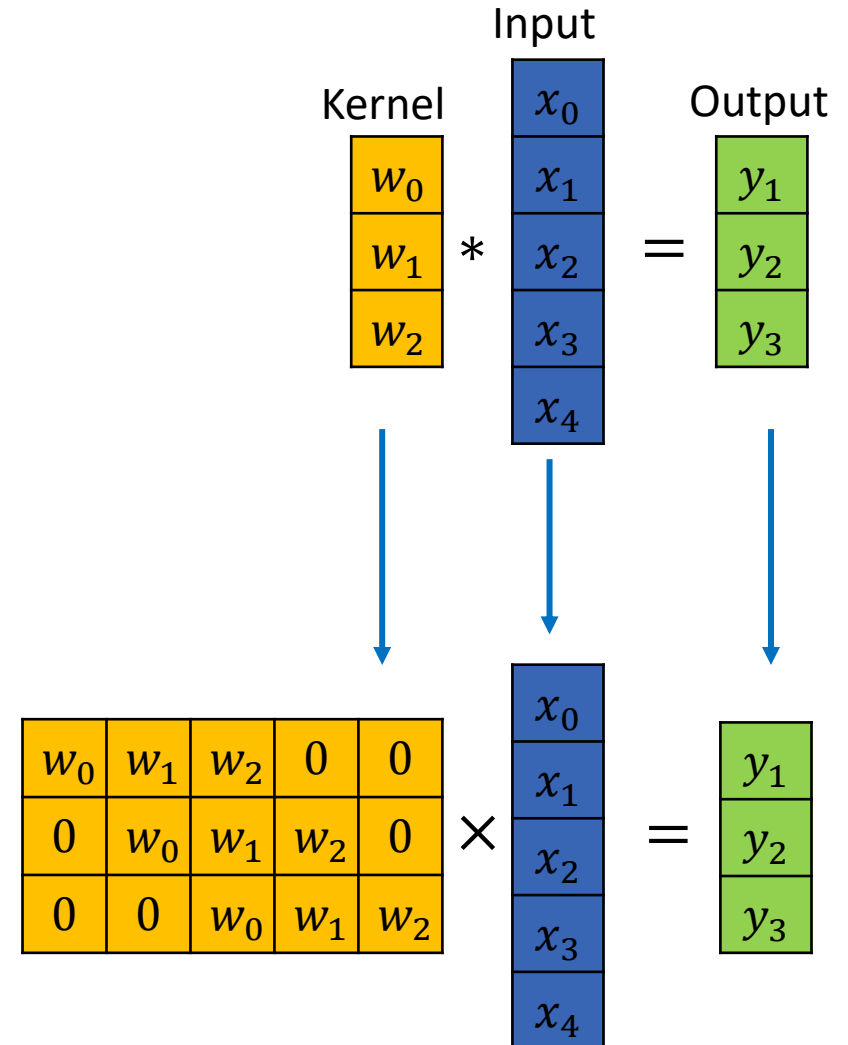

# 3D Convolution

- 3D filter slides along all 3 axes (width, height, depth). Very computation intensive
- Useful for 3D images such as medical CT/MRI images, or Point Clouds from Lidar

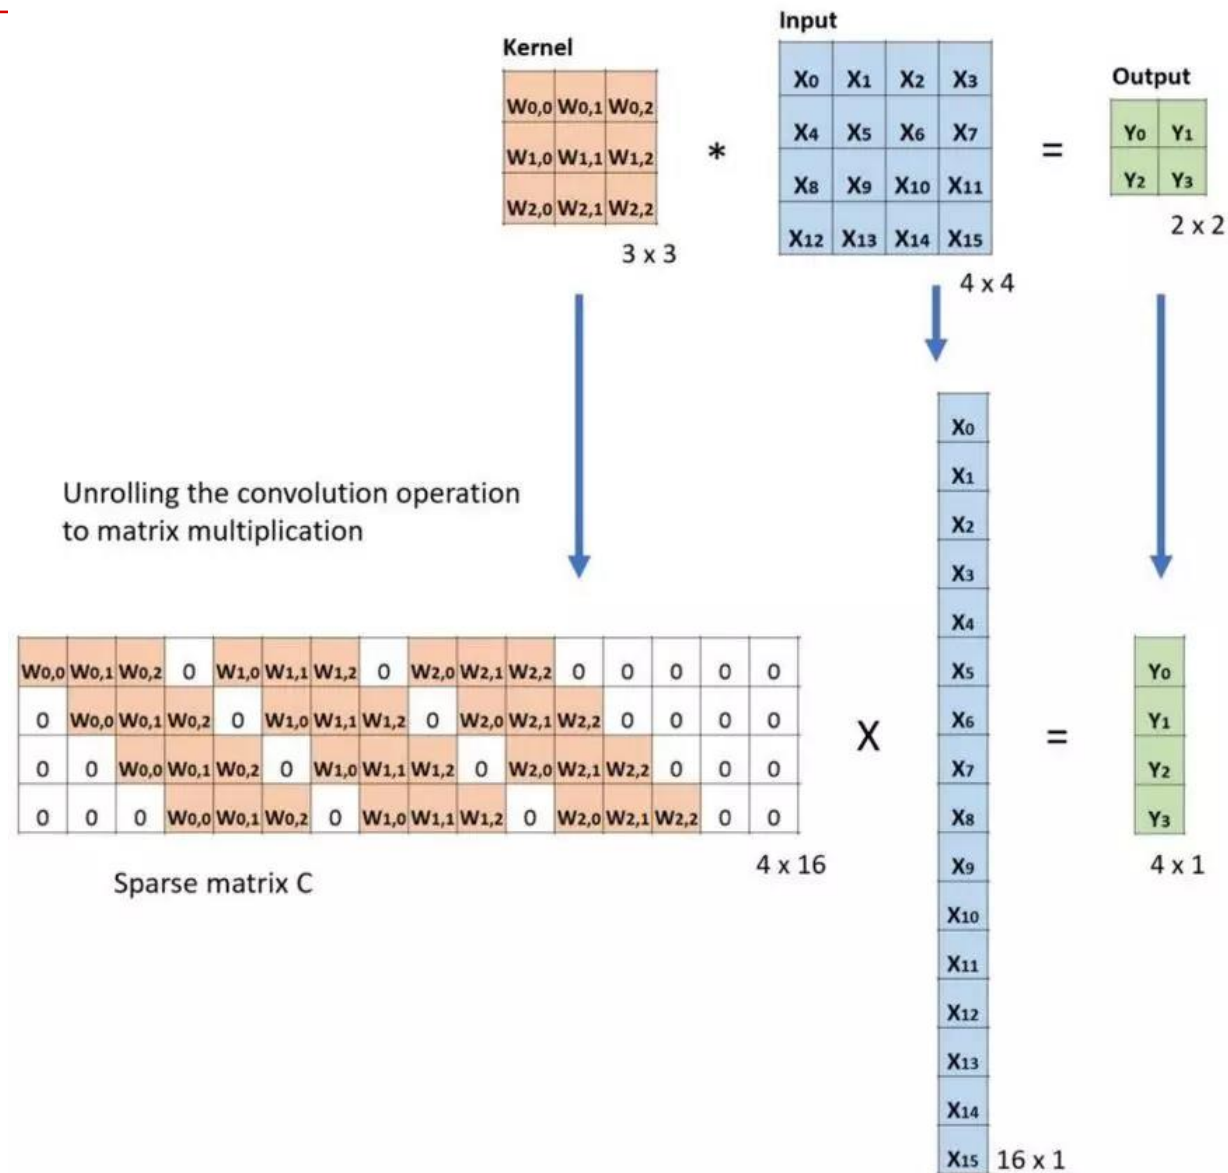

# Converting Convolution to Matrix Multiplication: 1D CONV Example

- Since parallel hardware (GPU, FPGA...) can handle matrix multiplication efficiently, this conversion increases computation efficiency at the expense of increased memory size for storing the weights (Biases are not shown in fig)

# Converting Convolution to Matrix Multiplication: 2D CONV Example

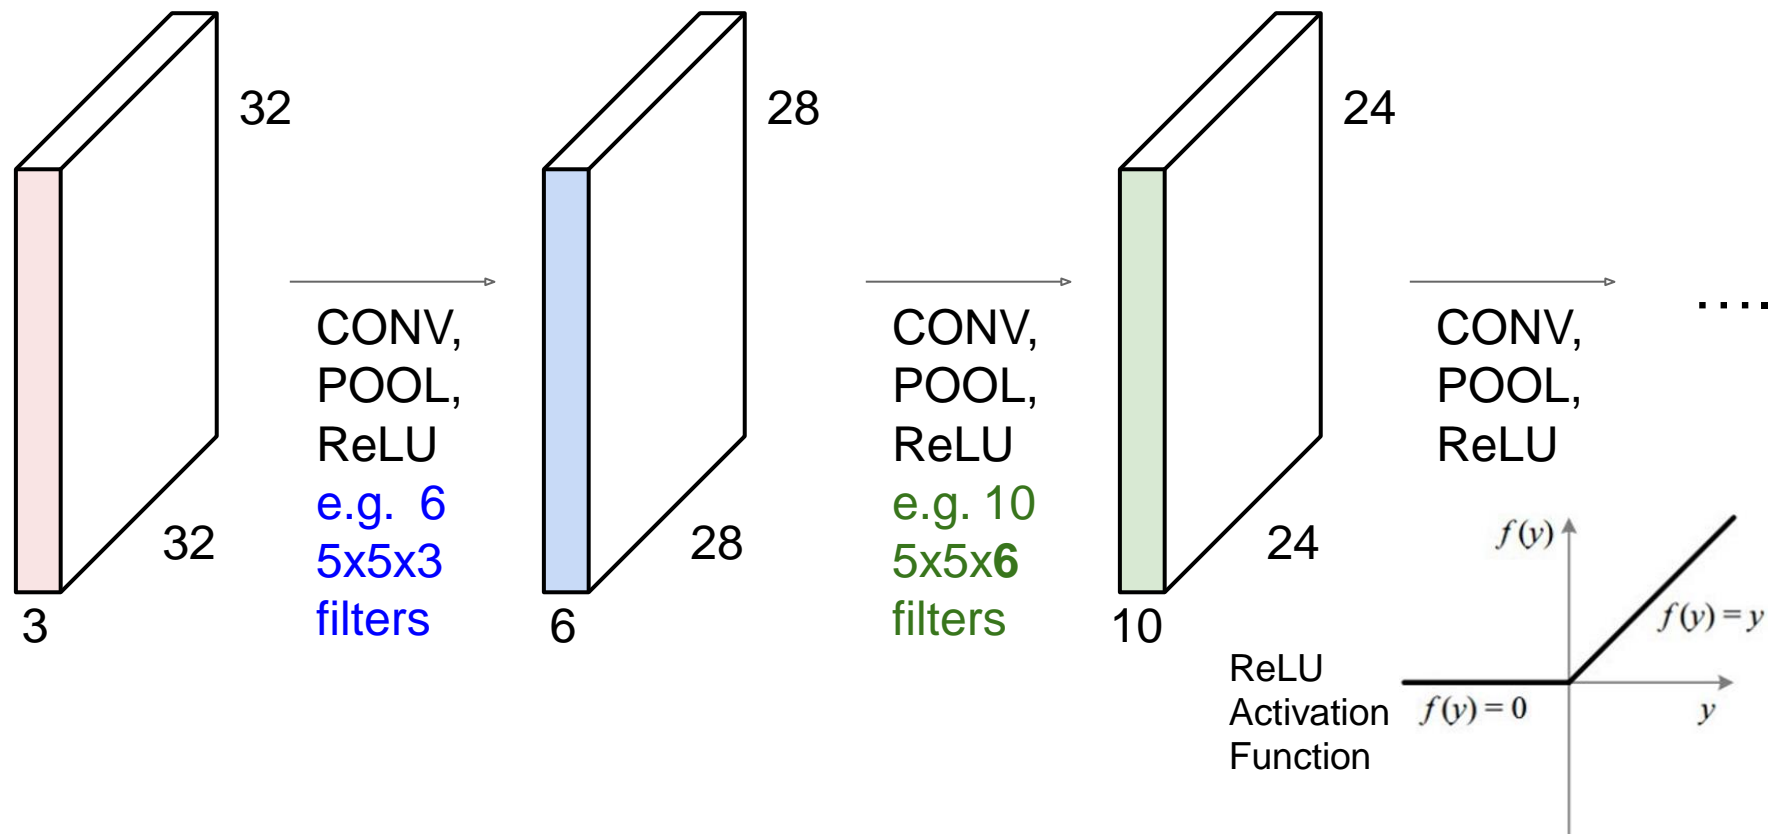

# Outline

---

- CNN Convolution layers
- Pooling and Fully-Connected layers
- Well-known CNN architectures

# Typical CNN Architecture

- Multiple layers, each consisting of CONV, POOL and non-linear activation functions (e.g., ReLU), are stacked into a deep network
  - Many variants possible, e.g., multiple CONV layers can be stacked without POOL and activation functions in-between

# Pooling (Sub-Sampling) Layer

- Accepts a volume of size  $W_1 \times H_1 \times D_1$
- Requires two hyperparameters:
  - their spatial extent  $F$ ,
  - the stride  $S$ ,
- Produces a volume of size  $W_2 \times H_2 \times D_2$  where:
  - $W_2 = (W_1 - F)/S + 1$
  - $H_2 = (H_1 - F)/S + 1$
  - $D_2 = D_1$
- Introduces zero parameters since it computes a fixed function of the input
- For Pooling layers, it is not common to pad the input using zero-padding.
- A pooling filter has depth 1, and operates over each activation map independently, hence the input volume and output volume have the same depth  $D_1 = D_2$ 
  - In contrast, a CONV filter has the same depth  $D_1$  as its input volume, and the number of filters  $K$  equals the depth  $D_2$  of its output volume
  - Common settings:  $F = 2, S = 2$ , or  $F = 3, S = 2$
- Example: pooling w. a  $2 \times 2$  filter w. stride  $S = 2$ , no pad. Output volume:  $\frac{W_1}{2} \times \frac{H_1}{2} \times D_1$  (since  $\frac{1}{2}(W_1 - 2) + 1 = \frac{W_1}{2}, \frac{1}{2}(H_1 - 2) + 1 = \frac{H_1}{2}$ )

# Max Pooling w. Examples

- Max pooling: take the max element among the  $F * F$  elements in each  $F \times F$  patch of each input activation map to reduce its dimension ( $F = 2, S = 2$ )
- Alternative: average pooling is less commonly used
- Pooling is also called subsampling or downsampling
  - Max pooling selects the brighter pixels from the image. It is useful when the background of the image is dark and we are interested in only the lighter pixels of the image.
  - Average pooling method smooths out the image and hence the sharp features may not be identified when this pooling method is used

# Overlapping Pooling

- Input volume:  $N \times N \times D_1$
- A  $3 \times 3$  pooling filter w. stride  $S = 1$ , no pad
- Output volume:  $(N - 2) \times (N - 2) \times D_1$  (since  $\frac{1}{1}(N - 3) + 1 = N - 2$ )
  - In practice, it is more common to have  $F = 3, S = 2$  for overlapping pooling

# Fully-Connected Layer

- Each neuron connects to the entire input volume w. no weight sharing
  - No. params for FC layer of size  $N_{out}$  connected to input layer of size  $N_{in}$  is  $(N_{in} + 1) * N_{out}$

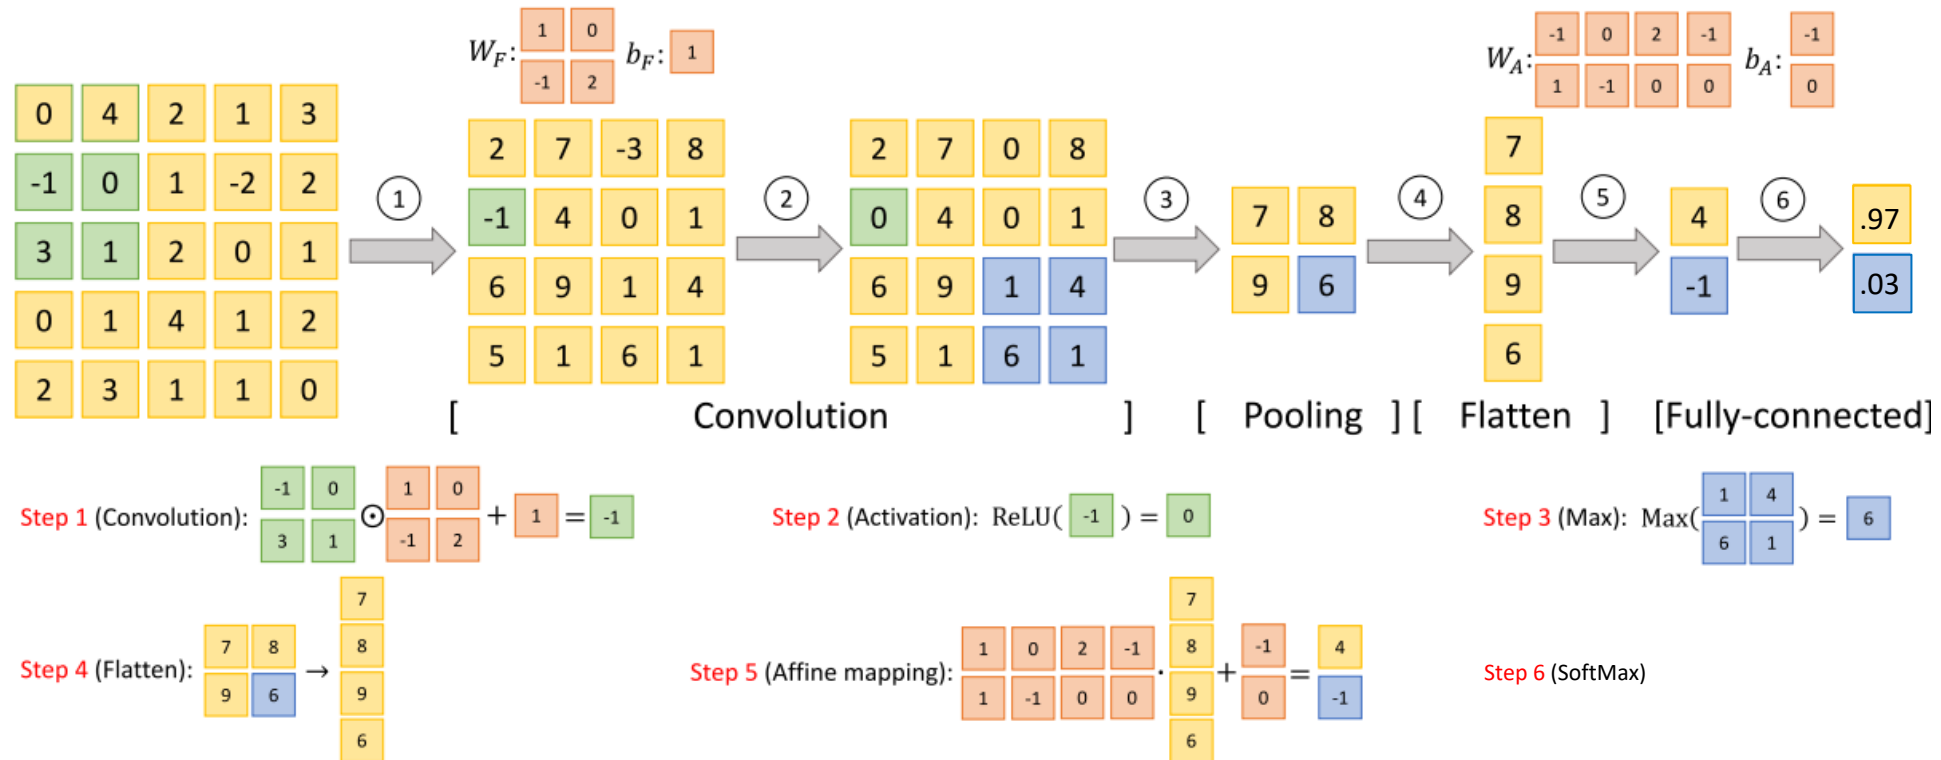

# A Complete CNN Example

- A CNN with a CONV layer, a FC layer and a SoftMax layer

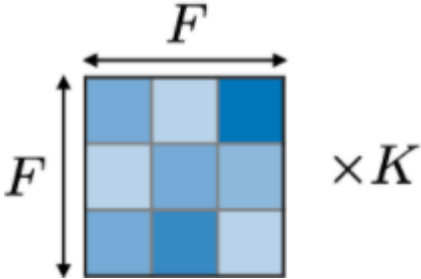

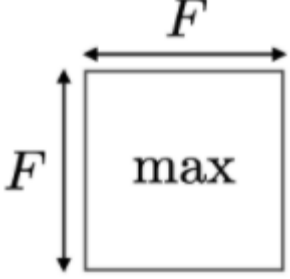

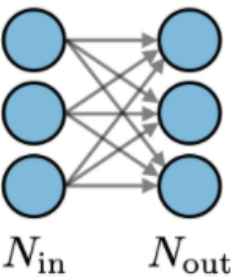

- Step 6 (SoftMax):

- Logits:  $[4, -1]$

- SoftMax scores  $[\frac{2^4}{2^4+2^{-1}}, \frac{2^{-1}}{2^4+2^{-1}}] = [.97, .03]$

# Summary of 3 Types of CNN Layers

	CONV	POOL	FC
			
Input volume	$W_1 \times H_1 \times D_1$	$W_1 \times H_1 \times D_1$	$N_{in}$
Output volume	$W_2 \times H_2 \times K$	$W_2 \times H_2 \times K$	$N_{out}$
No. params	$(F * F * D_1 + 1) * K$	0	$(N_{in} + 1) * N_{out}$
No. MULs	$(F * F * D_1 + 1) * K * W_2 * H_2$	0	$(N_{in} + 1) * N_{out}$

- (1) No. MULs for CONV layer:  $(F * F * D_1 + 1)$  MULs to compute each output element;  $K * W_2 * H_2$  output elements
- (2) Bias term of +1 is often omitted

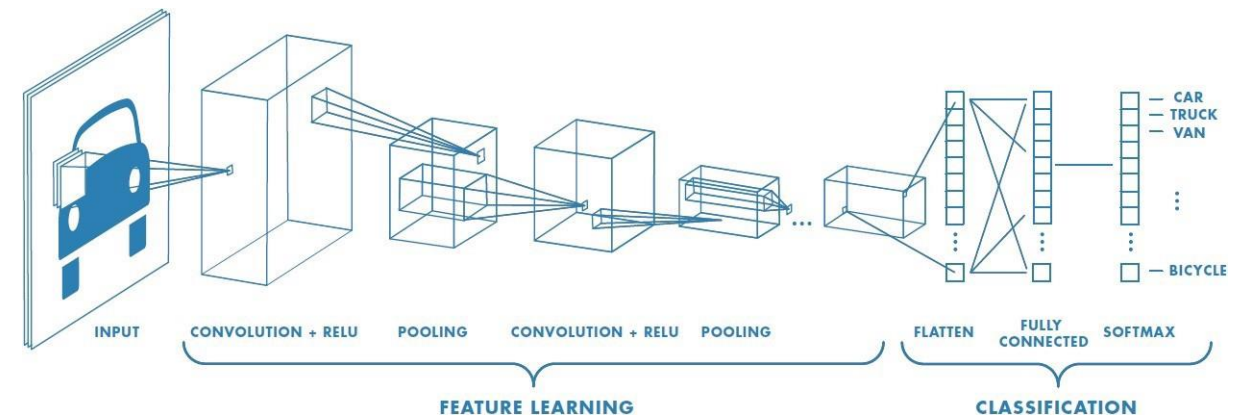

# Fully-Connected NN vs. CNN

- In a FCNN, all layers are Fully-Connected
- Cannot alter input image size
- No translation invariance
- No. params can grow very large, prone to overfitting

- In a CNN, only the last few (typically  $\leq 3$ ) layer(s) are FC
- CONV layers can handle images of arbitrary size
- Translation invariance
- Fewer params than MLP

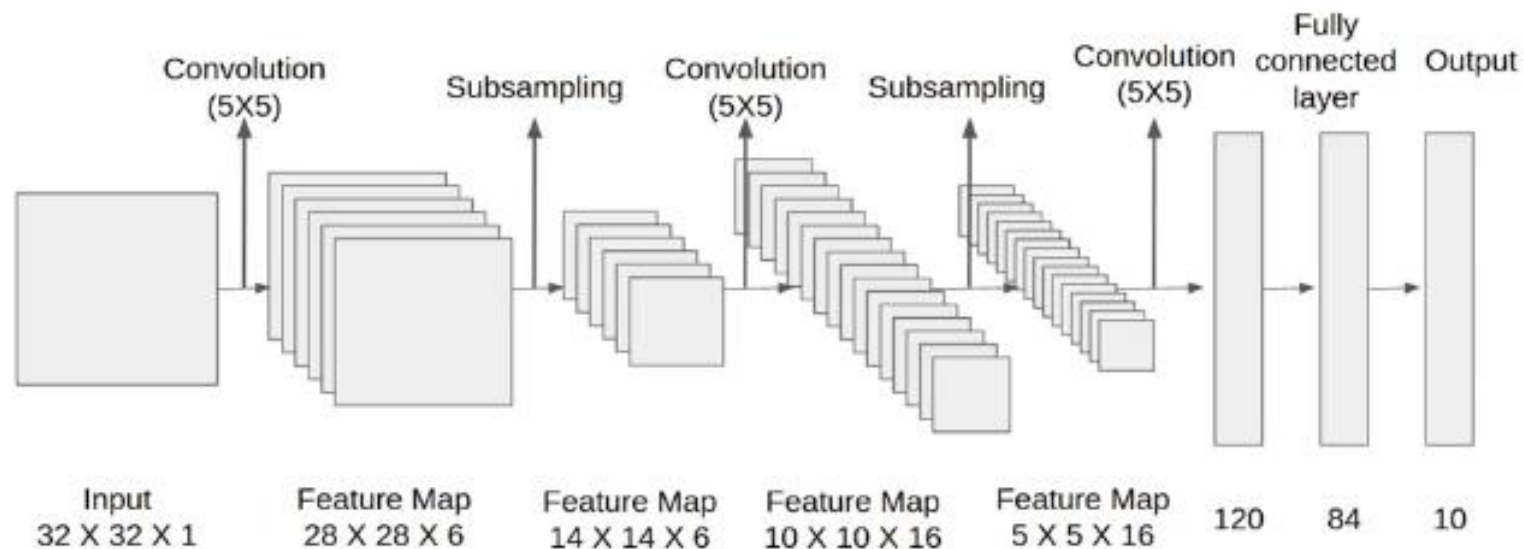

# Outline

# LeNet-5 Details

- Input image:  $32 \times 32 \times 1$  (grey-scale images of hand-written digits w. size  $32 \times 32$  pixels)
- Conv filters  $5 \times 5 \times 1$  w. stride 1; Pooling filters  $2 \times 2$  w. stride 2
- Conv layer C1 maps from input volume  $32 \times 32 \times 1$  to 6 feature maps w. volume  $28 \times 28 \times 6$  (since  $\frac{1}{1}(32 - 5) + 1 = 28$ ). No params:  $(5 * 5 * 1 + 1) * 6 = 156$
- Pooling layer S2 maps from input volume  $28 \times 28 \times 6$  to 6 feature maps w. volume  $14 \times 14 \times 6$  (since  $\frac{1}{2}(28 - 2) + 1 = 14$ ).
- Conv layer C3 maps from input volume  $14 \times 14 \times 6$  to 16 feature maps w. volume  $10 \times 10 \times 16$  (since  $\frac{1}{1}(14 - 5) + 1 = 10$ ). No params:  $(5 * 5 * 6 + 1) * 16 = 2416$
- Pooling layer S4 maps from input volume  $10 \times 10 \times 16$  to 16 feature maps w. volume  $5 \times 5 \times 16$  (since  $\frac{1}{2}(10 - 2) + 1 = 5$ )
- Conv layer C5 maps from input volume  $5 \times 5 \times 16$  to 120 feature maps w. volume  $1 \times 1 \times 120$  (since  $\frac{1}{1}(5 - 5) + 1 = 1$ ). No params:  $(5 * 5 * 16 + 1) * 120 = 48120$ 
  - You can also view it as an equivalent Fully-Connected layer that maps from the flattened input of size  $400 \times 1$  ( $5 * 5 * 16 = 400$ ) to output of size  $120 \times 1$ . For details, refer to L4.2 “Turning FC layer into CONV Layers”
- FC layer F6 maps from input of size  $120 \times 1$  to output of size  $84 \times 1$ . No params:  $(120 + 1) * 84 = 10164$
- Output layer (SoftMax) maps from input of size  $84 \times 1$  to output of size 10. No params:  $(84 + 1) * 10 = 850$

# ImageNet Large Scale Visual Recognition Challenge

- 1,000 object classes, 1.4 M labeled images

# AlexNet [Krizhevsky et al. 2012]

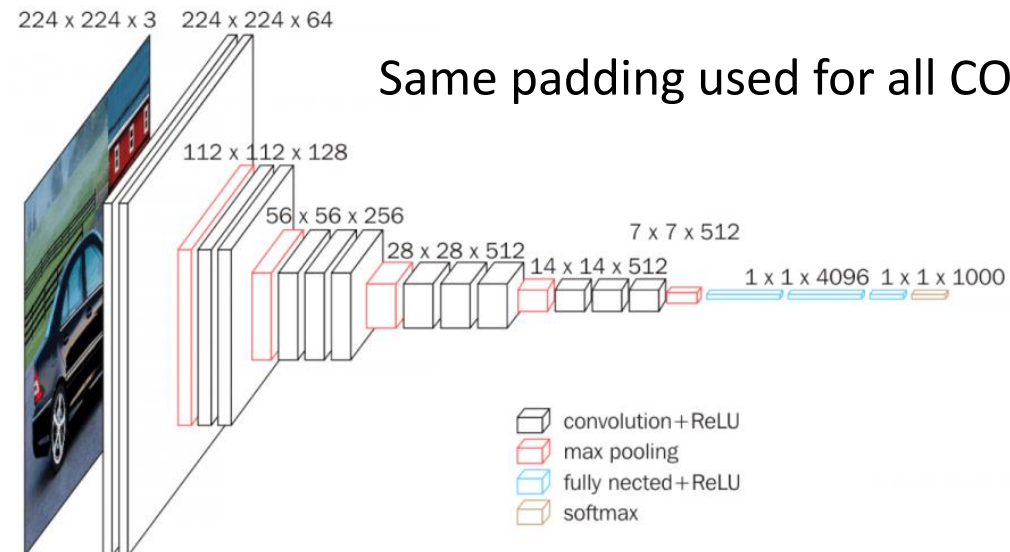

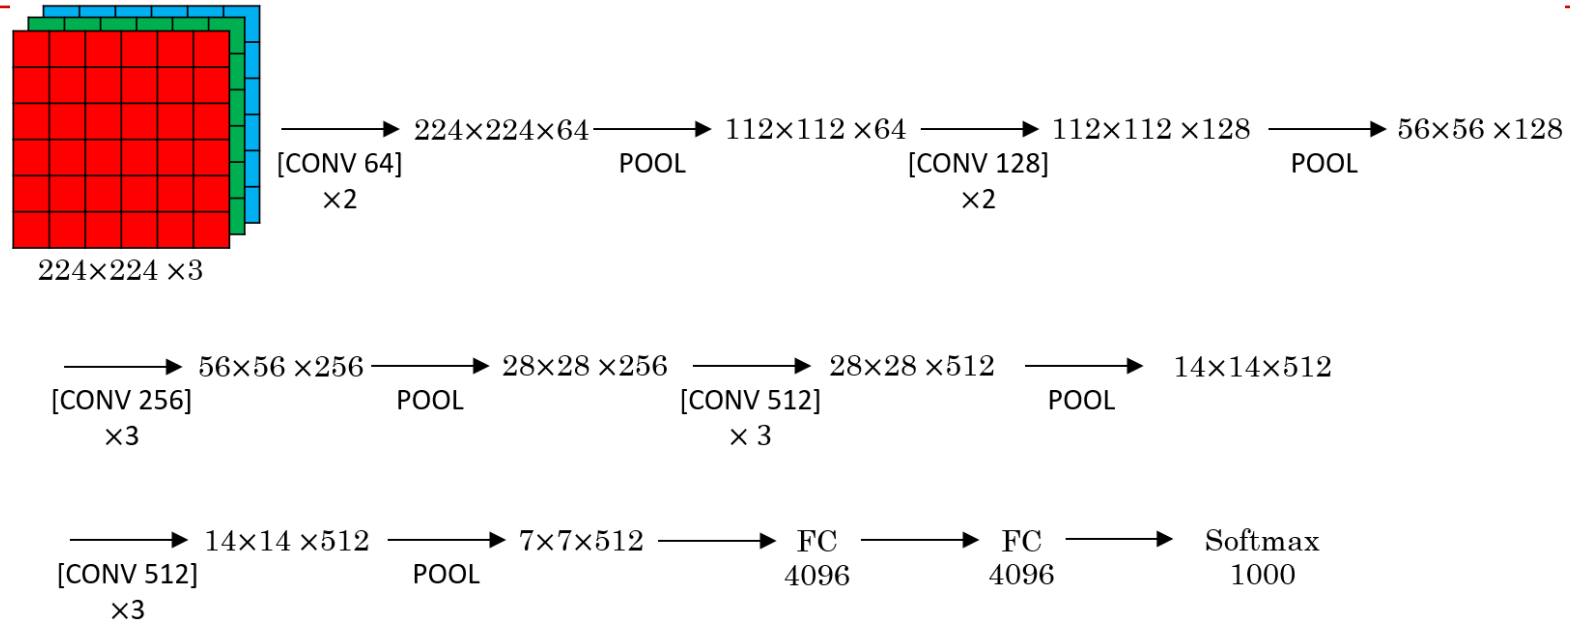

- Input image:  $227 \times 227 \times 3$
- 1<sup>st</sup> layer (CONV1): 96  $11 \times 11$  filters w. stride  $S = 4$ , w. ReLU activation function
- Output volume:  $55 \times 55 \times 96$  (since  $\frac{1}{4}(227 - 11) + 1 = 55$ ).
- 2<sup>nd</sup> layer (POOL1):  $3 \times 3$  filters w. stride  $S = 2$  (overlapping)
- Output volume:  $27 \times 27 \times 96$  (since  $\frac{1}{2}(55 - 3) + 1 = 27$ )
- ...
- Total # params: 60M
- Introduced ReLU activation function

# VGGNet [Simonyan 2014] (the best performing variant VGG-16)

CONV =  $3 \times 3$  filter,  $s = 1$ , same

MAX-POOL =  $2 \times 2$ ,  $s = 2$

# VGG-16 Details

- VGG-16 has 16 weight layers, not including POOL layers w. 0 weight
- Input image:  $224 \times 224 \times 3$
- 1<sup>st</sup> and 2<sup>nd</sup> CONV layers: 64  $3 \times 3$  filters w. stride  $S = 1$ , pad  $P = 1$ 
  - Output volume:  $224 \times 224 \times 64$  (since  $\frac{1}{1}(224 + 2 * 1 - 3) + 1 = 224$ )
- 3<sup>rd</sup> POOL layer:  $2 \times 2$  filters w. stride  $S = 2$ 
  - Output volume:  $112 \times 112 \times 64$  (since  $\frac{1}{2}(224 - 2) + 1 = 112$ )
- 4<sup>th</sup> and 5<sup>th</sup> CONV layers: 128  $3 \times 3$  filters w. stride  $S = 1$ , pad  $P = 1$ 
  - Output volume:  $112 \times 112 \times 128$  (since  $\frac{1}{1}(112 + 2 * 1 - 3) + 1 = 112$ )
- 6<sup>th</sup> POOL layer:  $2 \times 2$  filters w. stride  $S = 2$ 
  - Output volume:  $56 \times 56 \times 128$  (since  $\frac{1}{2}(112 - 2) + 1 = 56$ )
- Total # params: 60M
- ImageNet top 5 error: 7.3%

# Stacked $3 \times 3$ CONV Layers

- 2 stacked  $3 \times 3$  CONV layers w. pad  $P = 1$  have the same effective receptive field as a  $5 \times 5$  CONV layer; 3 stacked  $3 \times 3$  CONV layers w. pad  $P = 1$  have RF of  $7 \times 7$ ;  $L$  stacked  $3 \times 3$  CONV layers w. pad  $P = 1$  have RF of  $1 + 2L$ . Benefits:
  - Fewer params. Suppose all volumes have the same depth  $D$ , then a  $7 \times 7$  CONV layer has  $(7 * 7 * D + 1) * D \approx 49D^2$  params, while three stacked  $3 \times 3$  CONV layers have only  $(3 * 3 * D + 1) * D * 3 \approx 27D^2$  params
  - Two layers of non-linear activation functions increases CNN depth, hence larger model capacity

# GoogLeNet [Szegedy et al., 2014]

Additional classification heads  
for regularization

Inception Module

# Inception Module

- Can't make up your mind about filter size? Have them all in the Inception Module!
  - But this increases computation load
- Additional  $1 \times 1$  CONV layers serve as bottleneck to reduce number of parameters and computation load

- Without the bottleneck layer: No. params:  $5 * 5 * 192 * 32 = 153600$ ; No. MULs:  $(5 * 5 * 192) * (32 * 28 * 28) = 120\text{M}$

- With the bottleneck layer: No. params:  $1 * 1 * 192 * 16 + 5 * 5 * 16 * 32 = 15872$ ; No. MULs:  $(1 * 1 * 192) * (16 * 28 * 28) + (5 * 5 * 16) * (32 * 28 * 28) = 12.4\text{M}$

# GoogLeNet Size

- Compared to AlexNet:
  - 12x less params (only 5M, due to no FC layers), 2x more compute (due to more CONV layers)

# Xception [Chollet 2017] MobileNets [Howard et al. 2017] : Depthwise Separable Convolution

Each filter is convolved with all input channels

Regular Convolution

- Intermediate feature maps serve as bottleneck to reduce number of parameters and computation load
- Depthwise Separable Convolution - A FASTER CONVOLUTION!  
<https://www.youtube.com/watch?v=T7o3xvJLuHk>

# Example: Regular Convolution

No. params:  $3 * 3 * 2 * 4 = 72$   
(Four  $3 \times 3 \times 2$  filters) (not counting biases)

No. MULs:  $(3 * 3 * 2) * (4 * 4 * 4) = 1152$  ( $3 * 3 * 2$  MULs to compute each output element;  $4 * 4 * 4$  output elements)

# Example: Depthwise Separable Convolution

## 1. Depthwise Convolution

No. params:  $3 * 3 * 2 + 2 * 4 = 26$  (Two  $3 \times 3 \times 1$  filters and four  $1 \times 1 \times 2$  filters) (not counting biases)

No. MULs:  $(3 * 3 * 1) * (2 * 4 * 4) + (1 * 1 * 2) * (4 * 4 * 4) = 416$

## 2. Pointwise Convolution

(Depthwise Conv:  $3 * 3 * 1$  MULs to compute each output element;  $2 * 4 * 4$  output elements; Pointwise Conv:  $1 * 1 * 2$  MULs to compute each output element;  $4 * 4 * 4$  output elements)

# Residual Networks (ResNet) [He et al. 2015]

- In a standard network, output from a given layer is  $F(x)$
- In ResNet w. the identity skip (or short-cut) connection, output from a given layer is  $H(x) = F(x) + x$
- Benefits:
  - Residual connections help in handling the vanishing gradient problem in very deep NNs
  - If identity mapping is close to optimal, then weights can be small to capture minor differences only, in other words, “unnecessary layers” can learn to be identity mapping. This allows stacking many layers (e.g., 152) without overfitting

## • Residual net

# Deeper Nets have Better Performance

## CIFAR-10 experiments

# CNN Layer Patterns

- A typical CNN architecture looks like:  $\text{INPUT} \rightarrow [ [\text{CONV} \rightarrow \text{RELU}] * N \rightarrow \text{POOL?}] * M \rightarrow [ \text{FC} \rightarrow \text{RELU} ] * K \rightarrow \text{FC}$ 
  - where  $*$  indicates repetition, and  $\text{POOL?}$  indicates an optional pooling layer.  $N \geq 0$  (usually  $N \leq 3$ ),  $M \geq 0$ ,  $K \geq 0$  (and usually  $K < 3$ )
- Some common architectures:
  - $\text{INPUT} \rightarrow \text{FC}$ , implements a linear classifier. Here  $N = M = K = 0$ .
  - $\text{INPUT} \rightarrow \text{CONV} \rightarrow \text{RELU} \rightarrow \text{FC}$
  - $\text{INPUT} \rightarrow [ \text{CONV} \rightarrow \text{RELU} \rightarrow \text{POOL} ] * 2 \rightarrow \text{FC} \rightarrow \text{RELU} \rightarrow \text{FC}$  (fig below). There is a single CONV layer between every POOL layer.
  - $\text{INPUT} \rightarrow [ \text{CONV} \rightarrow \text{RELU} \rightarrow \text{CONV} \rightarrow \text{RELU} \rightarrow \text{POOL} ] * 3 \rightarrow [ \text{FC} \rightarrow \text{RELU} ] * 2 \rightarrow \text{FC}$  There are two CONV layers stacked before every POOL layer, e.g., two stacked  $3 \times 3$  CONV Layers. This is generally a good idea for larger and deeper networks, because multiple stacked CONV layers can develop more complex features of the input volume before the destructive pooling operation

# Layer Sizing Rules-of-Thumb

- The input layer (that contains the image) should be divisible by 2 many times. Common numbers include 32 (e.g. CIFAR-10), 64, 96 (e.g. STL-10), or 224 (e.g. ImageNet), 384, and 512
- The CONV layers should use small filters (e.g. 3x3 or at most 5x5), stride  $S=1$ . The input volume should have “same padding”, i.e., the conv layer does not alter the spatial size of the input. For any  $F$ , pad  $P=(F-1)/2$  preserves the input size, e.g., when  $F=3$ ,  $P=1$ ; when  $F=5$ ,  $P=2$ . This means the CONV layers only transform the input volume depth-wise, but do not perform downsampling. (c.f. CONV Example 3 and VGGNet)
- The POOL layers are in charge of downsampling the spatial dimensions of the input. The most common setting is to use max-pooling with 2x2 receptive fields ( $F=2$ ), with stride of 2 ( $S=2$ ). A less common setting is to use  $F=3$ ,  $S=2$ . It is uncommon to see receptive field sizes for max pooling that are larger than 3, because the pooling is then too lossy and aggressive
- In some cases (especially in early layers), the memory size can build up very quickly with the rules of thumb presented above. For example, filtering a 224x224x3 image with three 3x3 CONV layers with 64 filters each and padding 1 would create 3 activation volumes, each with size 224x224x64. This amounts to a total of about 10 million activations, or 72MB of memory (per image, for both activations and gradients). Since GPUs are often bottlenecked by memory, it may be necessary to compromise. In practice, make the compromise at only the first CONV layer that is looking at the input image, e.g., AlexNet uses filter size of 11x11 and stride of 4 in the first CONV layer

# Memory Size Considerations

---

- From intermediate volume sizes:
  - These are the raw number of activations at every layer of the CNN, and also their gradients (of equal size). Usually, most of the activations are on the earlier CONV layers of a CNN. These are kept around because they are needed for backpropagation during training, but for inference, we can store only the current activations at the current layer and discarding the activations from previous layers
- From parameter sizes:
  - These are the weights and biases, and their gradients during backprop, and also a step cache if the optimization is using momentum, Adagrad, or RMSProp. Therefore, the memory to store the parameter vector alone usually should be multiplied by a factor of at least 3 or so
- Each number may need 4 B storage space for floating point, 8 B for double, or 1 B or smaller for optimized fixed-point implementations

# Transfer Learning

- Instead of training your CNN from scratch, start from a pre-trained CNN (e.g., ResNet) and fine-tune it for your task
- First, replace SoftMax layer (classification head) with your own
- Next, train the CNN while keeping parameters frozen for
  - all CONV layers and only train the FC layer
  - or part of the earlier CONV layers close to the input layer (since earlier layers extract lower-level features that are more likely to be common among different tasks)
  - or none of the layers
- The decision depends on how much training data you have, and how similar your task is to that of the pre-trained CNN
